Preamble

Since 1980, the American College of Cardiology (ACC) and American Heart Association (AHA) have translated scientific evidence into clinical practice guidelines (guidelines) with recommendations to improve cardiovascular health. These guidelines, which are based on systematic methods to evaluate and classify evidence, provide a cornerstone for quality cardiovascular care. The ACC and AHA sponsor the development and publication of guidelines without commercial support, and members of each organization volunteer their time to the writing and review efforts. Guidelines are official policy of the ACC and AHA.

Intended Use

Practice guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a global impact. Although guidelines may be used to inform regulatory or payer decisions, their intent is to improve patients’ quality of care and align with patients’ interests. Guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances and should not replace clinical judgment.

Clinical Implementation

Guideline recommended management is effective only when followed by healthcare providers and patients. Adherence to recommendations can be enhanced by shared decision making between healthcare providers and patients, with patient engagement in selecting interventions based on individual values, preferences, and associated conditions and comorbidities.

Methodology and Modernization

The ACC/AHA Task Force on Clinical Practice Guidelines (Task Force) continuously reviews, updates, and modifies guideline methodology on the basis of published standards from organizations including the Institute of Medicine (1, 2) and on the basis of internal reevaluation. Similarly, the presentation and delivery of guidelines are reevaluated and modified on the basis of evolving technologies and other factors to facilitate optimal dissemination of information at the point of care to healthcare professionals. Given time constraints of busy healthcare providers and the need to limit text, the current guideline format delineates that each recommendation be supported by limited text (ideally, <250 words) and hyperlinks to supportive evidence summary tables. Ongoing efforts to further limit text are underway. Recognizing the importance of cost-value considerations in certain guidelines, when appropriate and feasible, an analysis of the value of a drug, device, or intervention may be performed in accordance with the ACC/AHA methodology (3).

To ensure that guideline recommendations remain current, new data are reviewed on an ongoing basis, with full guideline revisions commissioned in approximately 6-year cycles. Publication of new, potentially practice-changing study results that are relevant to an existing or new drug, device, or management strategy will prompt evaluation by the Task Force, in consultation with the relevant guideline writing committee, to determine whether a focused update should be commissioned. For additional information and policies regarding guideline development, we encourage readers to consult the ACC/AHA guideline methodology manual (4) and other methodology articles (5-8).
Selection of Writing Committee Members
The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds. Writing committee members represent different geographic regions, sexes, ethnicities, races, intellectual perspectives/biases, and scopes of clinical practice. The Task Force may also invite organizations and professional societies with related interests and expertise to participate as partners, collaborators, or endorsers.

Relationships With Industry and Other Entities
The ACC and AHA have rigorous policies and methods to ensure that guidelines are developed without bias or improper influence. The complete relationships with industry and other entities (RWI) policy can be found at http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy. Appendix 1 of the current document lists writing committee members’ relevant RWI. For the purposes of full transparency, writing committee members’ comprehensive disclosure information is available online at http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000509/-/DC1. Comprehensive disclosure information for the Task Force is available at http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/guidelines-and-documents-task-forces.

Evidence Review and Evidence Review Committees
When developing recommendations, the writing committee uses evidence-based methodologies that are based on all available data (4-7). Literature searches focus on randomized controlled trials (RCTs) but also include registries, nonrandomized comparative and descriptive studies, case series, cohort studies, systematic reviews, and expert opinion. Only key references are cited.

An independent evidence review committee (ERC) is commissioned when there are 1 or more questions deemed of utmost clinical importance that merit formal systematic review. This systematic review will strive to determine which patients are most likely to benefit from a drug, device, or treatment strategy and to what degree. Criteria for commissioning an ERC and formal systematic review include: a) the absence of a current authoritative systematic review, b) the feasibility of defining the benefit and risk in a time frame consistent with the writing of a guideline, c) the relevance to a substantial number of patients, and d) the likelihood that the findings can be translated into actionable recommendations. ERC members may include methodologists, epidemiologists, healthcare providers, and biostatisticians. When a formal systematic review has been commissioned, the recommendations developed by the writing committee on the basis of the systematic review are marked with “SR”.

Guideline-Directed Management and Therapy
The term guideline-directed management and therapy (GDMT) encompasses clinical evaluation, diagnostic testing, and pharmacological and procedural treatments. For these and all recommended drug treatment regimens, the reader should confirm the dosage by reviewing product insert material and evaluate the treatment regimen for contraindications and interactions. The recommendations are limited to drugs, devices, and treatments approved for clinical use in the United States.

Class of Recommendation and Level of Evidence
The Class of Recommendation (COR) indicates the strength of the recommendation, encompassing the estimated magnitude and certainty of benefit in proportion to risk. The Level of Evidence (LOE) rates the
quality of scientific evidence that supports the intervention on the basis of the type, quantity, and consistency of data from clinical trials and other sources (Table 1) (4-6).

Glenn N. Levine, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines
1. Introduction

The purpose of this focused update is to update the “2013 ACCF/AHA Guideline for the Management of Heart Failure” (9) (2013 HF guideline) in areas in which new evidence has emerged since its publication. For this update and future heart failure (HF) guidelines, the Heart Failure Society of America (HFSA) has partnered with the ACC and AHA to provide coordinated guidance on the management of HF.

The scope of the focused update includes revision to the sections on biomarkers; new therapies indicated for stage C HF with reduced ejection fraction (HFrEF); updates on HF with preserved ejection fraction (HFrEF); new data on important comorbidities, including sleep apnea, anemia, and hypertension; and new insights into the prevention of HF.

This focused update represents the second part of a 2-stage publication; with the first part having been published as the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure” (10), which introduced guidance on new therapies, specifically for the use of an angiotensin receptor–neprilysin inhibitor (ARNI) (valsartan/sacubitril) and a sinoatrial node modulator (ivabradine). That focused update was published concurrently with the European Society of Cardiology’s complete guideline, “2016 ESC Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure” (11).

1.1. Methodology and Evidence Review

To identify key data that influence guideline recommendations, the Task Force and members of the 2013 HF guideline writing committee reviewed clinical trials that were presented at the annual scientific meetings of the ACC, AHA, and European Society of Cardiology and other scientific meetings and that were published in peer-reviewed format from April 2013 through November 2016. The evidence is summarized in tables in the Online Data Supplement (http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000509/-/DC2). All recommendations (new, modified, and unchanged) for each clinical section are included to provide a comprehensive assessment. The text explains new and modified recommendations, whereas recommendations from the previous guideline that have been deleted or superseded no longer appear. Please consult the full-text version of the 2013 HF guideline (9) for text and evidence tables supporting the unchanged recommendations and for clinical areas not addressed in this focused update. Individual recommendations in this focused update will be incorporated into the full-text guideline in the future. Recommendations from the prior guideline that remain current have been included for completeness, but the LOE reflects the COR/LOE system used when the recommendations were initially developed. New and modified recommendations in this focused update reflect the latest COR/LOE system, in which LOE...
B and C are subcategorized for greater specificity (4-6). The section numbers correspond to the full-text guideline sections.

1.2. Organization of the Writing Group

For this focused update, representative members of the 2013 HF guideline writing committee were invited to participate. They were joined by additional invited members to form a new writing group, which is referred to as the 2017 HF focused update writing group. Members were required to disclose all RWI relevant to the data under consideration. The group was composed of experts representing general cardiologists, HF and transplantation specialists, electrophysiologists, pharmacists, and general internists. The 2017 HF focused update writing group included representatives from the ACC, AHA, and HFSA, as well as the American Academy of Family Physicians, American College of Chest Physicians, American College of Physicians, and International Society for Heart and Lung Transplantation.

1.3. Document Review and Approval

The focused update was reviewed by 2 official reviewers each nominated by the ACC, AHA, and HFSA; 1 reviewer each from the American Academy of Family Physicians, American College of Chest Physicians, and International Society for Heart and Lung Transplantation; and 19 individual content reviewers. Reviewers’ RWI information is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACC, AHA, and HFSA.

</table>

COR and LOE are determined independently (any COR may be paired with any LOE).
A recommendation with LOE C does not imply that the recommendation is weak. Many important clinical questions addressed in guidelines do not lend themselves to clinical trials. Although RCTs are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

* The outcome or result of the intervention should be specified (an improved clinical outcome or increased diagnostic accuracy or incremental prognostic information).

† For comparative-effectiveness recommendations (COR I and IIa; LOE A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

‡ The method of assessing quality is evolving, including the application of standardized, widely used, and preferably validated evidence grading tools; and for systematic reviews, the incorporation of an Evidence Review Committee.

COR indicates Class of Recommendation; EO, expert opinion; LD, limited data; LOE, Level of Evidence; NR, nonrandomized; R, randomized; and RCT, randomized controlled trial.
6. Initial and Serial Evaluation of the HF Patient

6.3. Biomarkers

Assays for BNP (B-type natriuretic peptide) and NT-proBNP (N-terminal pro-B-type natriuretic peptide), which are both natriuretic peptide biomarkers, have been used increasingly to establish the presence and severity of HF. In general, both natriuretic peptide biomarker values track similarly, and either can be used in patient care settings as long as their respective absolute values and cutpoints are not used interchangeably. Notably, BNP, but not NT-proBNP, is a substrate for neprilysin. Therefore, ARNI increases BNP levels (12) but not NT-proBNP levels (13). Note that the type of natriuretic peptide assay that has been performed must be considered during interpretation of natriuretic peptide biomarker levels in patients on ARNI. In 2 studies with ARNI, NT-proBNP levels were reduced (12, 14), with the reduction in 1 study being associated with improved clinical outcomes (12).

A substantial evidence base exists that supports the use of natriuretic peptide biomarkers to assist in the diagnosis or exclusion of HF as a cause of symptoms (e.g., dyspnea, weight gain) in the setting of chronic ambulatory HF (15-21) or in the setting of acute care with decompensated HF (22-30), especially when the cause of dyspnea is unclear. The role of natriuretic peptide biomarkers in population screening to detect incident HF is emerging (31-37). Elevated plasma levels of natriuretic peptide biomarkers are associated with a wide variety of cardiac and noncardiac causes (Table 2) (38-42). Obesity may be associated with lower natriuretic peptide concentrations, and this may modestly reduce diagnostic sensitivity in morbidly obese patients (42).

Because of the absence of clear and consistent evidence for improvement in mortality and cardiovascular outcomes (43-62), there are insufficient data to inform specific guideline recommendations related to natriuretic peptide–guided therapy or serial measurements of BNP or NT-proBNP levels for the purpose of reducing hospitalization or deaths in the present document.

Like natriuretic peptides, cardiac troponin levels may be elevated in the setting of chronic or acute decompensated HF, suggesting myocyte injury or necrosis (63). Troponins I and T respond similarly for acute coronary syndromes and acute decompensated HF. Elevations in either troponin I or T levels in the setting of acute HF are of prognostic significance and must be interpreted in the clinical context (64).

In addition to natriuretic peptides and troponins (65-67), multiple other biomarkers, including those of inflammation, oxidative stress, vascular dysfunction, and myocardial and matrix remodeling, have been implicated in HF (68-71). Biomarkers of myocardial fibrosis, soluble ST2 receptor, and galectin-3 are predictive of hospitalization and death and may provide incremental prognostic value over natriuretic peptide levels in patients with HF (72-74). Strategies that combine multiple biomarkers may
ultimately prove beneficial in guiding HF therapy in the future, but multicenter studies with larger derivation and validation cohorts are needed (75, 76). Several emerging biomarkers await validation with well-defined outcome measures and prognostic accuracy before they can reach the clinical arena (77-84).

This section categorizes the role of biomarkers into prevention, diagnosis, prognosis, and added risk stratification to clarify evidence-based objectives of their use in clinical practice.

</tbody>
</table>

In a large-scale unblinded single-center study (STOP-HF [The St Vincent’s Screening to Prevent Heart Failure]) (85), patients at risk of HF (identified by the presence of hypertension, diabetes mellitus, or known vascular disease [e.g., stage A HF]), but without established left ventricular systolic dysfunction or symptomatic HF at baseline, were randomly assigned to receive screening with BNP testing or usual primary care. Intervention-group participants with BNP levels of $\geq 50$ pg/mL underwent echocardiography and were referred to a cardiovascular specialist who decided on further investigation and management. All patients received further coaching by a specialist nurse who emphasized individual risk and the importance of adherence to medication.
and healthy lifestyle behaviors. BNP-based screening reduced the composite endpoint of asymptomatic left ventricular dysfunction (systolic or diastolic) with or without newly diagnosed HF (85). Similarly, in another small, single-center RCT, accelerated up-titration of renin-angiotensin-aldosterone system antagonists and beta blockers reduced cardiac events in patients with diabetes mellitus and elevated NT-proBNP levels but without cardiac disease at baseline (86). Developing a standardized strategy to screen and intervene in patients at risk of HF can be difficult because of different definitions of HF risk, heterogeneity of prevalence in different populations, variable duration until clinical HF or left ventricular dysfunction develops, and variable interventions for risk factor modification or treatment. Further studies are needed to determine cost-effectiveness and risk of such screening, as well as its impact on quality of life (QoL) and mortality rate.

6.3.2. Biomarkers for Diagnosis: Recommendation

<table>

<td>A</td>
<td>In patients presenting with dyspnea, measurement of natriuretic peptide biomarkers is useful to support a diagnosis or exclusion of HF (15-24, 28-30).</td>
<td>MODIFIED: 2013 acute and chronic recommendations have been combined into a diagnosis section.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>See Online Data Supplements A and B.</td>
<td></td>
</tr>
</tbody>
</table>

Natriuretic peptide biomarker testing in the setting of chronic ambulatory HF provides incremental diagnostic value to clinical judgment, especially when the etiology of dyspnea is unclear (15-21). In emergency settings, natriuretic peptide biomarker levels usually have higher sensitivity than specificity and may be more useful for ruling out than ruling in HF (20). Although lower values of natriuretic peptide biomarkers exclude the presence of HF, and higher values have reasonably high positive predictive value to diagnose HF, clinicians should be aware that elevated plasma levels for both natriuretic peptides have been associated with a wide variety of cardiac and noncardiac causes (Table 2) (38-41).

6.3.3. Biomarkers for Prognosis or Added Risk Stratification: Recommendations

<table>
<thead>
<tr>
<th>Biomarkers: Recommendations for Prognosis</th>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
<td>A</td>
<td>Measurement of BNP or NT-proBNP is useful for establishing prognosis or disease severity in chronic HF (16, 87-92).</td>
<td>2013 recommendation remains current.</td>
</tr>
<tr>
<td>See Online Data Supplements A and B.</td>
<td>I</td>
<td>A</td>
<td>Measurement of baseline levels of natriuretic peptide biomarkers and/or cardiac troponin on admission to the hospital is useful to establish a prognosis in acutely decompensated HF (27, 93-100).</td>
<td>MODIFIED: Current recommendation emphasizes that it is admission levels of natriuretic peptide biomarkers that are useful.</td>
</tr>
</tbody>
</table>

Higher levels of natriuretic peptide biomarkers on admission are usually associated with greater risk for clinical outcomes, including all-cause and cardiovascular mortality, morbidity, and composite outcomes, across different time intervals in patients with decompensated HF (20, 27, 29, 93-101). Similarly, abnormal levels of circulating cardiac troponin are commonly found in patients with acute decompensated HF, often without obvious
myocardial ischemia or underlying coronary artery disease (CAD), and this is associated with worse clinical outcomes and higher risk of death (95, 99, 102, 103).

Studies have demonstrated incremental prognostic value of these biomarkers to standard approaches of cardiovascular disease risk assessment (29, 95). However, there were differences in the risk prediction models, assay cutpoints, and lengths of follow-up (29). Furthermore, not all patients may need biomarker measurement for prognostication, especially if they already have advanced HF with established poor prognosis or persistently elevated levels of biomarkers in former settings. Therefore, assays of natriuretic peptide biomarkers for incremental prognostication should not preclude good clinical judgment; an individualized approach to each patient is paramount.

<table>
<thead>
<tr>
<th>IIa</th>
<th>B-NR</th>
<th>During a HF hospitalization, a predischarge natriuretic peptide level can be useful to establish a postdischarge prognosis (93, 96, 104-113).</th>
<th>NEW: Current recommendation reflects new observational studies.</th>
</tr>
</thead>
</table>

Predischarge natriuretic peptide biomarker levels and the relative change in levels during hospital treatment are strong predictors of the risk of death or hospital readmission for HF (93, 96, 104-113). Several studies have suggested that predischarge natriuretic peptide biomarker levels had higher reclassification and discrimination value than clinical variables in predicting outcomes (96, 106, 108-111). Patients with higher predischarge levels and patients who do not have a decrease in natriuretic peptide biomarker levels during hospitalization have worse outcomes (96, 106, 108-111). Although observational or retrospective studies have suggested that patients with natriuretic peptide biomarker reduction had better outcomes than those without any changes or with a biomarker rise (93, 107, 112, 113), targeting a certain threshold, value, or relative change in these biomarker levels during hospitalization may not be practical or safe for every patient and has not been tested in a prospective large-scale trial. Clinical assessment and adherence to GDMT should be the emphasis, and the prognostic value of a predischarge value or relative changes does not imply the necessity for serial and repeated biomarker measurements during hospitalization.

<table>
<thead>
<tr>
<th>IIb</th>
<th>B-NR</th>
<th>In patients with chronic HF, measurement of other clinically available tests, such as biomarkers of myocardial injury or fibrosis, may be considered for additive risk stratification (27, 95, 98, 99, 103, 114-119).</th>
<th>MODIFIED: 2013 recommendations have been combined into prognosis section, resulting in LOE change from A to B-NR.</th>
</tr>
</thead>
</table>

Biomarkers of myocardial fibrosis (e.g., soluble ST2 receptor, galectin-3, high-sensitivity cardiac troponin, and others) are predictive of hospitalization and death in patients with HF and also are additive to natriuretic peptide biomarker levels in their prognostic value (117, 119-126). A combination of biomarkers may ultimately prove to be more informative than single biomarkers (127).
Figure 1. Biomarkers Indications for Use

Colors correspond to COR in Table 1.

Angiotensin-converting enzyme (ACE) inhibitors reduce morbidity and mortality in heart failure with reduced ejection fraction (HFrEF). Randomized controlled trials (RCTs) clearly establish the benefits of ACE inhibition in patients with mild, moderate, or severe symptoms of HF and in patients with or without coronary artery disease (128-133). ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough but also may contribute to their beneficial effect through vasodilation.

Angiotensin receptor blockers (ARBs) were developed with the rationale that angiotensin II production continues in the presence of ACE inhibition, driven through alternative enzyme pathways. ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema than ACE inhibitors; but like ACE inhibitors, ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium. Long-term therapy with ARBs produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system and have been shown in RCTs (134-137) to reduce morbidity and mortality, especially in ACE inhibitor–intolerant patients.

In ARNI, an ARB is combined with an inhibitor of neprilysin, an enzyme that degrades natriuretic peptides, bradykinin, adrenomedullin, and other vasoactive peptides. In an RCT that compared the first approved ARNI, valsartan/sacubitril, with enalapril in symptomatic patients with HFrEF tolerating an adequate dose of either ACE inhibitor or ARB, the ARNI reduced the composite endpoint of cardiovascular death or HF hospitalization significantly, by 20% (138). The benefit was seen to a similar extent for both death and HF hospitalization and was consistent across subgroups. The use of ARNI is associated with the risk of hypotension and renal insufficiency and may lead to angioedema, as well.

See Online Data Supplements 1, 2, 18-20.
The use of ACE inhibitors is beneficial for patients with prior or current symptoms of chronic HFrEF to reduce morbidity and mortality (128-133, 143).

ACE inhibitors have been shown in large RCTs to reduce morbidity and mortality in patients with HFrEF with mild, moderate, or severe symptoms of HF, with or without coronary artery disease (128-133). Data suggest that there are no differences among available ACE inhibitors in their effects on symptoms or survival (143). ACE inhibitors should be started at low doses and titrated upward to doses shown to reduce the risk of cardiovascular events in clinical trials. ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium (>5.0 mEq/L). Angioedema occurs in <1% of patients who take an ACE inhibitor, but it occurs more frequently in blacks and women (144). Patients should not be given ACE inhibitors if they are pregnant or plan to become pregnant. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough in up to 20% of patients but also may contribute to beneficial vasodilation. If maximal doses are not tolerated, intermediate doses should be tried; abrupt withdrawal of ACE inhibition can lead to clinical deterioration and should be avoided.

Although the use of an ARNI in lieu of an ACE inhibitor for HFrEF has been found to be superior, for those patients for whom ARNI is not appropriate, continued use of an ACE inhibitor for all classes of HFrEF remains strongly advised.

The use of ARBs to reduce morbidity and mortality is recommended in patients with prior or current symptoms of chronic HFrEF who are intolerant to ACE inhibitors because of cough or angioedema (134-137, 145, 146).

ARBs have been shown to reduce mortality and HF hospitalizations in patients with HFrEF in large RCTs (134-137). Long-term therapy with ARBs in patients with HFrEF produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system (145, 146). Unlike ACE inhibitors, ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema, although kininase inhibition by ACE inhibitors may produce beneficial vasodilatory effects.

Patients intolerant to ACE inhibitors because of cough or angioedema should be started on ARBs; patients already tolerating ARBs for other indications may be continued on ARBs if they subsequently develop HF. ARBs should be started at low doses and titrated upward, with an attempt to use doses shown to reduce the risk of cardiovascular events in clinical trials. ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium (>5.0 mEq/L). Although ARBs are
Alternatives for patients with ACE inhibitor–induced angioedema, caution is advised because some patients have also developed angioedema with ARBs. Head-to-head comparisons of an ARB versus ARNI for HF do not exist. For those patients for whom an ACE inhibitor or ARNI is inappropriate, use of an ARB remains advised.

| I | ARNI: B-R | In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality (138). | NEW: New clinical trial data necessitated this recommendation. |

See Online Data Supplements 1 and 18.

Benefits of ACE inhibitors with regard to decreasing HF progression, hospitalizations, and mortality rate have been shown consistently for patients across the clinical spectrum, from asymptomatic to severely symptomatic HF. Similar benefits have been shown for ARBs in populations with mild-to-moderate HF who are unable to tolerate ACE inhibitors. In patients with mild-to-moderate HF (characterized by either 1) mildly elevated natriuretic peptide levels, BNP [B-type natriuretic peptide] >150 pg/mL or NT-proBNP [N-terminal pro-B-type natriuretic peptide] ≥600 pg/mL; or 2) BNP ≥100 pg/mL or NT-proBNP ≥400 pg/mL with a prior hospitalization in the preceding 12 months) who were able to tolerate both a target dose of enalapril (10 mg twice daily) and then subsequently an ARNI (valsartan/sacubitril; 200 mg twice daily, with the ARB component equivalent to valsartan 160 mg), hospitalizations and mortality were significantly decreased with the valsartan/sacubitril compound compared with enalapril. The target dose of the ACE inhibitor was consistent with that known to improve outcomes in previous landmark clinical trials (129). This ARNI has been approved for patients with symptomatic HFrEF and is intended to be substituted for ACE inhibitors or ARBs. HF effects and potential off-target effects may be complex with inhibition of the neprilysin enzyme, which has multiple biological targets. Use of an ARNI is associated with hypotension and a low-frequency incidence of angioedema. To facilitate initiation and titration, the approved ARNI is available in 3 doses that include a dose that was not tested in the HF trial; the target dose used in the trial was 97/103 mg twice daily (147). Clinical experience will provide further information about the optimal titration and tolerability of ARNI, particularly with regard to blood pressure, adjustment of concomitant HF medications, and the rare complication of angioedema (14).

| III: Harm | B-R | ARNI should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor (148, 149). | NEW: Available evidence demonstrates a potential signal of harm for a concomitant use of ACE inhibitors and ARNI. |
Oral neprilysin inhibitors, used in combination with ACE inhibitors can lead to angioedema and concomitant use is contraindicated and should be avoided. A medication that represented both a neprilysin inhibitor and an ACE inhibitor, omapatrilat, was studied in both hypertension and HF, but its development was terminated because of an unacceptable incidence of angioedema (148, 149) and associated significant morbidity. This adverse effect was thought to occur because both ACE and neprilysin break down bradykinin, which directly or indirectly can cause angioedema (149, 150). An ARNI should not be administered within 36 hours of switching from or to an ACE inhibitor.

### Harm

<td><em><em>Ivabradine can be beneficial to reduce HF hospitalization for patients with symptomatic (NYHA class II-III) stable chronic HFREF (LVEF ≤35%) who are receiving GDEM</em>, including a beta blocker at maximum tolerated dose, and who are in sinus rhythm with a heart rate of 70 bpm or greater at rest (154-157).</em>*</td>
<td>NEW: New clinical trial data.</td>
</tr>
</tbody>
</table>

Omapatrilat, a neprilysin inhibitor (as well as an ACE inhibitor and aminopeptidase P inhibitor), was associated with a higher frequency of angioedema than that seen with enalapril in an RCT of patients with HFREF (148). In a very large RCT of hypertensive patients, omapatrilat was associated with a 3-fold increased risk of angioedema as compared with enalapril (149). Blacks and smokers were particularly at risk. The high incidence of angioedema ultimately led to cessation of the clinical development of omapatrilat (151, 152). In light of these observations, angioedema was an exclusion criterion in the first large trial assessing ARNI therapy in patients with hypertension (153) and then in the large trial that demonstrated clinical benefit of ARNI therapy in HFREF (138). ARNI therapy should not be administered in patients with a history of angioedema because of the concern that it will increase the risk of a recurrence of angioedema.

</tr>
</tbody>
</table>

Ivabradine is a new therapeutic agent that selectively inhibits the If current in the sinoatrial node, providing heart rate reduction. One RCT demonstrated the efficacy of ivabradine in reducing the composite endpoint of cardiovascular death or HF hospitalization (155). The benefit of ivabradine was driven by a reduction in HF hospitalization. The study included patients with HFREF (NYHA class II-IV, albeit with only a modest representation of NYHA class IV HF) and left ventricular ejection fraction (LVEF) ≤35%, in sinus rhythm with a resting heart rate of ≥70 beats per minute. Patients enrolled included a small number with paroxysmal atrial fibrillation (<40% of the time) but otherwise in
sinus rhythm and a small number experiencing ventricular pacing but with a predominant sinus rhythm. Those with a myocardial infarction within the preceding 2 months were excluded. Patients enrolled had been hospitalized for HF in the preceding 12 months and were on stable GDEM* for 4 weeks before initiation of ivabradine therapy. The target of ivabradine is heart rate slowing (the presumed benefit of action), but only 25% of patients studied were on optimal doses of beta-blocker therapy (9, 139, 140, 155). Given the well-proven mortality benefits of beta-blocker therapy, it is important to initiate and up titrate these agents to target doses, as tolerated, before assessing the resting heart rate for consideration of ivabradine initiation (155).

*In other parts of the document, the term “GDMT” has been used to denote guideline-directed management and therapy. In this recommendation, however, the term “GDEM” has been used to denote this same concept in order to reflect the original wording of the recommendation that initially appeared in the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure: An Update of the 2013 ACCF/AHA Guideline for the Management of Heart Failure” (10).
Figure 2. Treatment of HFrEF Stage C and D

Step 1

Establish Dx of HFrEF; assess volume; initiate GDMT

HFrEF
NYHA class I–IV
(Stage C)

Step 2

Consider the following patient scenarios

ACEI or ARB AND GDMT beta blocker; diuretics as needed (COR I)

NYHA class II–IV, provided est. CrCl >30 mL/min & K+ <5.0 mEq/L

Aldosterone antagonist (COR I)

Step 3

Implement indicated GDMT. Choices are not mutually exclusive, and no order is inferred

Discontinue ACEI or ARB; initiate ARNI* (COR I)

Step 4

Reassess symptoms

Step 5

Consider additional therapy

NYHA class II–III HF Adequate BP on ACEI or ARB*: No C/I to ARB or sacubitril

Hydral-Nitrates†‡ (COR I)

NYHA class II–III, LVEF ≤35%, (caveat: >1 y survival, >40 d post MI)

ICD‡ (COR I)

NYHA class II–IV, LVEF ≥150 ms with LBBB pattern

CRT or CRT-D‡ (COR I)

NYHA class II–III, NSR, heart rate ≥70 bpm on maximally tolerated dose beta blocker

Ivabradine (COR IIa)

NYHA class III–IV

<td>In appropriately selected patients with HFrEF (with EF ≥45%, elevated BNP levels or HF admission within 1 year, estimated glomerular filtration rate &gt;30 mL/min, creatinine &lt;2.5 mg/dL, potassium &lt;5.0 mEq/L), aldosterone receptor antagonists might be considered to decrease hospitalizations (83, 166, 167).</td>
<td>NEW: Current recommendation reflects new RCT data.</td>
</tr>
</tbody>
</table>

Mechanistic studies have suggested that mineralocorticoid receptor antagonists can improve measures of diastolic function in patients with HFrEF, possibly by a similar effect on remodeling (83, 168).

The TOPCAT (Treatment of Preserved Cardiac Function Heart Failure With an Aldosterone Antagonist) trial (166) investigated the effects of spironolactone on a combined endpoint of death, aborted cardiac death, and HF hospitalization in patients with HFrEF. A small reduction (HR=0.89) in this composite endpoint did not reach statistical significance, although HF hospitalization was reduced (HR=0.83); known side effects of hyperkalemia and rising creatinine were seen more commonly in the treatment group (166). An unusual amount of regional variation was seen in this trial, prompting a post-hoc analysis (167) that showed that rates of the primary endpoint were 4-fold lower in Russia/Georgia than in North America and South America (the Americas). Rates in the Americas were comparable to those in other HFrEF trials (169, 170). The post-hoc analysis showed efficacy in the Americas (HR=0.83) but not in Russia/Georgia (HR=1.10). Moreover, a sample of the Russia/Georgia population, despite having been in the active treatment arm, had nondetectable levels of
the metabolite of spironolactone. These post-hoc analyses have significant limitations, but they suggest that in appropriately selected patients with symptomatic HFpEF (with ejection fraction [EF] \(\geq\) 45\%), elevated BNP level or HF admission within 1 year, estimated glomerular filtration rate >30 mL/min creatinine <2.5 mg/dL, and potassium <5.0 mEq/L), particularly in those with elevated BNP levels, use of spironolactone might be considered with close monitoring of potassium and renal function. Confirmatory studies are required.

With regard to the use of mineralocorticoid receptor antagonists, creatinine should be <2.5 mg/dL in men or <2.0 mg/dL in women (or estimated glomerular filtration rate >30 mL/min) and potassium should be <5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing represents best practices at initiation and during follow-up thereafter to minimize risk of hyperkalemia and worsening renal function.

| IIb | B | Routine use of ARBs might be considered to decrease hospitalizations for patients with HFpEF (169). | 2013 recommendation remains current. |
| III: No Benefit | B-R | Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or QoL in patients with HFpEF is ineffective (171, 172). | NEW: Current recommendation reflects new data from RCTs. |

Nitrate therapy can reduce pulmonary congestion and improve exercise tolerance in patients with HFpEF. However, the NEAT-HFpEF (Nitrate’s Effect on Activity Tolerance in Heart Failure With Preserved Ejection Fraction) trial (171) randomized 110 patients with EF \(\geq\) 50\% on stable HF therapy, not including nitrates, and with activity limited by dyspnea, fatigue, or chest pain, to either isosorbide mononitrate or placebo and found no beneficial effects on activity levels, QoL, exercise tolerance, or NT-proBNP levels. On the basis of this trial, routine use of nitrates in patients with HFpEF is not recommended. This recommendation does not apply to patients with HFpEF and symptomatic CAD for whom nitrates may provide symptomatic relief.

Phosphodiesterase-5 inhibition augments the nitric oxide system by upregulating cGMP activity. The RELAX (Phosphodiesterase-5 Inhibition to Improve Clinical Status and Exercise Capacity in Heart Failure with Preserved Ejection Fraction) trial (172) randomized 216 patients with EF \(\geq\) 50\% on stable HF therapy and with reduced exercise tolerance (peak observed VO\(_2\) <60\% of predicted) to phosphodiesterase-5 inhibition with sildenafil or placebo. This study did not show improvement in oxygen consumption or exercise tolerance.

| III: No Benefit | C | Routine use of nutritional supplements is not recommended for patients with HFpEF. | 2013 recommendation remains current. |

9. Important Comorbidities in HF

9.2. Anemia: Recommendations

<table>
<thead>
<tr>
<th>Recommendations for Anemia</th>
</tr>
</thead>
<tbody>
<tr>
<td>COR</td>
</tr>
<tr>
<td>IIb</td>
</tr>
</tbody>
</table>

See Online Data Supplement D. Routine baseline assessment of all patients with HF includes an evaluation for anemia in addition to other baseline laboratory measurements. Anemia is independently associated with HF disease severity, and iron
deficiency appears to be uniquely associated with reduced exercise capacity. When iron deficiency is diagnosed and after full evaluation for cause, intravenous repletion of iron, especially in the setting of concomitant hepcidin deficiency in HF, may improve exercise capacity and QoL. Studies examining correction of iron deficiency in HF have demonstrated improvement in surrogate endpoints, such as QoL, NT-proBNP, and LVEF; however, controlled trials have been underpowered to detect reductions in hard clinical endpoints. The FAIR-HF (Ferric Carboxymaltose Assessment in Patients With Iron Deficiency and Chronic Heart Failure) trial (173) demonstrated improvements in NYHA class and functional capacity over a short-term exposure. The CONFIRM-HF (Ferric Carboxymaltose Evaluation on Performance in Patients With Iron Deficiency in Combination with Chronic Heart Failure) trial (174) included a larger cohort of patients (n=304) and demonstrated improvements in 6-minute walk test. A meta-analysis of 5 prospective controlled studies (631 patients) evaluated the effect of intravenous iron on deaths, hospitalizations, and other events in patients with HF and iron deficiency (175). Patients receiving intravenous iron experienced limited but statistically significant improvements in functional capacity and LVEF but no reduction in mortality rate. The FAIR-HF 2 trial is underway to further address the potential benefit of intravenous iron in HF associated with iron deficiency. Therefore, a strong recommendation for intravenous iron repletion must await the results of an appropriately powered trial on morbidity and mortality. There is an uncertain evidence base for oral iron repletion in the setting of anemia associated with HF.

Small studies evaluating the treatment of anemia in patients with HF have suggested a trend toward improvement in functional capacity and reduction in hospitalization with the use of erythropoietin-stimulating agents (177-182), but results have varied (183) and have been limited because of sample size. Although a meta-analysis of 11 RCTs (n=794) comparing erythropoietin-stimulating agents to control in patients with HF demonstrated significant improvements in 6-minute walk, exercise duration, peak VO₂, NYHA functional status, EF, BNP, HF-related hospitalizations, and QoL (184), in the STAMINA-HeFT (Study of Anemia in Heart Failure) trial (183), darbepoetin alfa was not associated with significant clinical benefits. In the largest RCT to date (n=2,278), correction of anemia with darbepoetin alfa did not result in benefit and resulted in a significant increase in the risk of thromboembolic events and a nonsignificant increase in fatal and nonfatal strokes, supporting findings from other trials (176, 185-188). In summary, the strongest evidence on erythropoietin-stimulating agent therapy in HF suggests lack of benefit and increased adverse events. Therefore, erythropoietin-stimulating agent therapy cannot be recommended in patients with HF and anemia.

<td>B-R</td>
<td>In patients at increased risk, stage A HF, the optimal blood pressure in those with hypertension should be</td>
<td><strong>NEW</strong>: Recommendation reflects new RCT data.</td>
</tr>
</tbody>
</table>
A large RCT demonstrated that in those with increased cardiovascular risk (defined as age >75 years, established vascular disease, chronic renal disease, or a Framingham Risk Score >15%), control of blood pressure to a goal systolic pressure of <120 mm Hg, as determined by blood pressure assessment as per research protocol, was associated with a significant reduction in the incidence of HF (191) and an overall decrease in cardiovascular death. Blood pressure measurements as generally taken in the office setting are typically 5 to 10 mm Hg higher than research measurements; thus, the goal of <130/80 mm Hg is an approximation of the target blood pressure in conventional practice. Targeting a significant reduction in systolic blood pressure in those at increased risk for cardiovascular disease is a novel strategy to prevent HF.

### 9.5.2. Treating Hypertension in Stage C HFrEF: Recommendation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-E0</td>
<td>Patients with HFrEF and hypertension should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg (191).</td>
<td>NEW: Recommendation has been adapted from recent clinical trial data but not specifically tested per se in a randomized trial of patients with HF.</td>
</tr>
</tbody>
</table>

Clinical trials evaluating goal blood pressure reduction and optimal blood pressure–lowering agents in the setting of HFrEF and concomitant hypertension have not been done. However, it is apparent that in those patients at higher risk, blood pressure lowering is associated with fewer adverse cardiovascular events. GDMT for HFrEF with agents known to lower blood pressure should consider a goal blood pressure reduction consistent with a threshold now associated with improved clinical outcomes but not yet proven by RCTs in a population with HF.

### 9.5.3. Treating Hypertension in Stage C HFpEF: Recommendation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-LD</td>
<td>Patients with HFpEF and persistent hypertension after management of volume overload should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg (167, 169, 170, 194-199).</td>
<td>NEW: New target goal blood pressure based on updated interpretation of recent clinical trial data.</td>
</tr>
</tbody>
</table>

The use of nitrates in the setting of HFpEF is associated with a signal of harm and, in most situations, should be avoided. For many common antihypertensive agents, including alpha blockers, beta blockers, and calcium channel blockers, there are limited data to guide the choice of antihypertensive therapy in the setting of HFpEF (172). Nevertheless, RAAS inhibition with ACE inhibitor, ARB (especially mineralocorticoid receptor antagonists), and possibly ARNI would represent the preferred choice. A shared decision-making discussion with the patient influenced by physician judgment should drive the ultimate choice of antihypertensive agents.
### 9.6. Sleep Disordered Breathing: Recommendations

*(Moved from Section 7.3.1.4, Treatment of Sleep Disorders in the 2013 HF guideline.)*

<table>
<thead>
<tr>
<th>Recommendations for Treatment of Sleep Disorders</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>COR</strong></td>
</tr>
<tr>
<td>IIa</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Sleep disorders are common in patients with HF. A study of adults with chronic HF treated with evidence-based therapies found that 61% had either central or obstructive sleep apnea (202). It is clinically important to distinguish obstructive sleep apnea from central sleep apnea, given the different responses to treatment. Adaptive servo-ventilation for central sleep apnea is associated with harm (203). Continuous positive airway pressure (CPAP) for obstructive sleep apnea improves sleep quality, reduces the apnea-hypopnea index, and improves nocturnal oxygenation (200, 201).

| IIb     | B-R     | In patients with cardiovascular disease and obstructive sleep apnea, CPAP may be reasonable to improve sleep quality and daytime sleepiness (204). | NEW: New data demonstrate the limited scope of benefit expected from CPAP for obstructive sleep apnea. |
|         |         | See Online Data Supplement G. | |

In patients with sleep apnea, a trial evaluated the impact of CPAP with usual therapy versus usual therapy alone on subsequent cardiovascular events, including HF (204). In this RCT of >2,700 patients, there was no evidence of benefit on cardiovascular events at a mean follow-up of 3.7 years for CPAP plus usual care compared with usual care alone. Improvements in sleep quality were noteworthy and represented the primary indication for initiating CPAP treatment (204). However, in patients with atrial fibrillation (AF) (a frequent comorbidity noted with HF), the use of CPAP for obstructive sleep apnea was helpful. In a trial of 10,132 patients with AF and obstructive sleep apnea, patients on CPAP treatment were less likely to progress to more permanent forms of AF than were patients without CPAP (205).

| III: Harm | B-R     | In patients with NYHA class II–IV HFrEF and central sleep apnea, adaptive servo-ventilation causes harm (203). | NEW: New data demonstrate a signal of harm when adaptive servo-ventilation is used for central sleep apnea. |
|          |         | See Online Data Supplement G. | |

Mortality rate (all cause and cardiovascular) was higher with adaptive servo-ventilation plus GDMT than with GDMT alone in a single RCT to test the addition of adaptive servo-ventilation (≥5 hours/night, 7 days/week) to GDMT in patients with HFrEF and central sleep apnea (203). A similar risk has been seen in another trial, and a third trial of adaptive servo-ventilation in central sleep apnea and HF was aborted because of ethical concerns. The weight of evidence does not support the use of adaptive servo-ventilation for central sleep apnea in HFrEF.

Novartis† 7.3.2.10, 7.3.2.11, 7.3.3, 9.2, and 9.5.

7.3.2.10, 7.3.2.11, 7.3.3, and 9.5.

7.3.2.10, 7.3.2.11, 7.3.3, and 9.5.

6.3, 7.3.2.10, 7.3.2.11, 7.3.3, 9.5, and 9.6.
This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of $\geq 5\%$ of the voting stock or share of the business entity, or ownership of $\geq $5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship if: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Significant relationship.

ACC indicates American College of Cardiology; ACCF, American College of Cardiology Foundation; AHA, American Heart Association; DCRI, Duke Clinical Research Institute; DSMB, data safety monitoring board; HFSA, Heart Failure Society of America; NHLBI, National Heart, Lung, and Blood Institute; INTERMACS, Interagency Registry for Mechanically Assisted Circulatory Support; PARENT, Pulmonary artery pressure reduction with entresto; UCLA, University of California, Los Angeles; and VA, Veterans Affairs.

This table represents all relationships of committee members with industry and other entities that were reported by authors, including those not deemed to be relevant to this document, at the time this document was under development. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no

person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship IF: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Significant relationship.

# 2017 Heart Failure Focused Update Data Supplement

*(Section numbers correspond to the 2013 full-text guideline.)*

## Table of Contents

| Data Supplement A. RCTs and Meta-analyses With Biomarkers (Section 6.3) | 3 |
| Data Supplement B. Nonrandomized Trials/Observational Studies/Registries for Changes in or Discharge NP Levels in ADHF – Biomarkers (Section 6.3) | 15 |
| Data Supplement 1. RCTs Comparing ARNI (Section 7.3.2.10) | 27 |
| Data Supplement 2. RCTs Comparing RAAS Inhibition (Section 7.3.2.3) | 29 |
| Data Supplement 3. RCTs Comparing Pharmacological Treatment for of ARNI With ACE (Section 7.3.2.10) | 31 |
| Data Supplement 4. RCTs Comparing Pharmacological Treatment for Stage C HF\(r\)EF (Section 7.3.2.11) | 33 |
| Data Supplement C. RCTs Comparing Pharmacologic Treatment for HF\(p\)EF: Recommendations (Section 7.3.3) | 36 |
| Data Supplement D. RCTs Comparing Anemia (Section 9.2) | 41 |
| Data Supplement E. RCTs Comparing HTN (Section 9.5) | 44 |
| Data Supplement F. Nonrandomized Trials for Hypertension (Section 9.5) | 50 |
| Data Supplement G. RCTs Comparing Treatment of Sleep Disorders (CPAP makers) (Section 9.6) | 51 |
| 2013 HF Guideline Data Supplement 18. ACE Inhibitors (Section 7.3.2.2) | 62 |
| 2013 HF Guideline Data Supplement 19. ARBs (Section 7.3.2.3) | 65 |
| 2013 HF Guideline Data Supplement 20. Beta Blockers (Section 7.3.2.4) | 66 |

| **PONTIAC** Huelsmann et al. 2013 (1) 23810874 | **Aim:** To assess the effectiveness of neurohumoral therapy for the prevention of cardiac events in pts with type 2 DM with increased biomarker NT-proBNP | **Inclusion criteria:** Pts with type 2 DM, age ≥18 y, elevated NT-proBNP (≥125 pg/mL) | **Intervention:** Individualized up-titration of RAS antagonists and beta blockers in addition to diabetes treatment (150), treated at cardiology clinic | **1º endpoint:** Hospitalization or death due to cardiac disease following 24 mo  
Results: Significant reduction of 1º endpoint in intervention group (HR: 0.351; 95% CI: 0.127–0.975; p=0.044)  
**1º Safety endpoint:** BP was significantly reduced in both intervention and control (p<0.05); heart rate was only reduced in the intensified group (p=0.004) | • All-cause hospitalizations, HF hospitalizations and unplanned CV hospitalizations or death (p<0.05 reduction)  
• Study limitations: Absence of pt randomization for treatment, pt population mainly Caucasian, statistical analysis done without adjustment of co-variates  
• Pts treated with a RAS antagonist/beta-blocker and the dosage reached higher in intensified group (p<0.0001)  
• No difference in NT-proBNP levels |
| **STOP-HF** Ledwidge et al. 2013 (2) 23821090 | **Aim:** To establish efficacy of BNP screening and collaborative care in at-risk population in reducing newly | **Inclusion criteria:** Pts ≥40 y, and history of HTN (on meds ≥1 mo), hypercholesterolemia, obesity, vascular disease including | **Intervention:** BNP screening at BL and annually and protocol referral for BNP ≥50 pg/mL for echocardiography and collaborative care. (697) | **1º endpoint:** LV dysfunction (systolic: LVEF <50% or diastolic: E/E’ ratio >15) with or without newly diagnosed HF(with symptoms of HF requiring admission to  
Emergency hospitalizations for major MACE [40 vs. 22 (0.60 OR; 95% CI: .45-0.81; p=.002)])  
CV investigations more likely to be done in the intervention group with BNP levels ≥50 pg/mL  
Increase in RAAS agents in the |

| **BATTLESCARRED**  
Lainchbury et al. 2009 (16)  
20117364 |
| **Aim:** to compare the effects of NT-proBNP-guided therapy with those of intensive clinical management and with usual care |
| **Study Type:** RCT (Australia hospitals) |
| **Size:** 364 pts |
| **Inclusion criteria:**  
Pts admitted to a single hospital with HF, NT-proBNP >50 pmoL/l or 400 pg/mL.(included HFpEF) |
| **Intervention:**  
Outpatient post d/c therapy guided by NT-proBNP levels  
Target: NT-proBNP <150 pmoL/l (1,270 pg/mL) |
| **Comparators:**  
Therapy guided by intensive clinical management, or according to usual care |
| **1° endpoints:**  
Mortality |
| **Results:**  
1-y mortality was less in both the hormone (9.1%) and clinically-guided (9.1%) groups compared with usual care (18.9%; p=0.03) |
| • 3 y mortality was selectively reduced in pts ≤75 y receiving hormone guided treatment (15.5%) compared with either clinically managed treatment (30.9%; p=0.048) or usual care (31.3%; p=0.021). |
| • NP guidance changed therapy |
| • NT-ProBNP levels were not different between groups |
| Berger et al. 2010 (17)  
20170790 |
| **Aim:** To investigate whether the addition of NT-proBNP-guided, intensive pt management to multidisciplinary care improves outcome in pts following hospitalization due to HF |
| **Inclusion criteria:**  
Pts admitted to a hospital with HF, NYHA III or IV on admission, Cardiothoracic Index>0.5 or LVEF <40% |
| **Intervention:**  
Outpatient post discharge discontinue  
BM: NT-proBNP-guided, intensive up-titration of medication by HF specialists in high-risk pts.  
• Target: NT-proBNP (<2,200 pg/mL) |
| **Comparators:**  
• Multidisciplinary care: 2 consultations from an HF |
| **1° endpoints:**  
Hospitalization |
| **Results:**  
• Pt management reduced HF hospitalization (488 D) compared with the multidisciplinary care (1254 D) and usual care (1,588 d) groups (p<0.0001)  
• Combined end point of death or HF rehospitalization was lower |
| • NT-ProBNP levels were not different between groups: Pt management group had the highest proportion of RAAS inhibition triple-therapy  
• Death rate was similar between the pt management (22%) and multidisciplinary care groups (22%), but was lower compared with the usual care group (39%; vs. pt management: p<0.02; vs. multidisciplinary care: p<0.02) |
<table>
<thead>
<tr>
<th>Study Type: RCT (8 Viennese hospitals)</th>
<th>Inclusion criteria: specialist-therapeutic recommendations and home care by a HF nurse • Usual care in the BM (37%) than in the multidisciplinary care group (50%; p&lt;0.05) and in the multidisciplinary care than in the usual care group (65%; p=0.04) • NT-ProBNP levels were lowered in guided pt management arm</th>

</tr>
<tr>
<td>van Kimmenade et al. 2006 (24) 16860029</td>
<td>Aim: To analyze the role of NT-pro-BNP in diagnosis of HF in pts presenting with dyspnea, the so-called natriuretic peptide gray zone. NT-pro-BNP concentrations, clinical characteristics, and 60-d mortality were studied in acutely dyspneic pts from an international</td>
<td>Inclusion criteria: Acutely dyspneic pts</td>
<td>Comparator: Non-HF pts such as pulmonary disease, cor pulmonale</td>
<td>Interventions: Comparisons of NT-pro-BNP among diagnostic groups including HF and non-HF pts</td>
<td>1° endpoint: Subjects with HF and diagnostically elevated NT-pro-BNP concentrations had the highest mortality rates, subjects without HF and NT-pro-BNP concentrations &lt; 300 ng/L had the lowest mortality rates, and subjects with gray-zone NT-pro-BNP had intermediate outcomes, irrespective of their final diagnoses.</td>
<td></td>
</tr>
</tbody>
</table>
### Maisel et al. 2004 (25) 15364340

**Aim:** To examine the relationships among BNP levels and HF severity, clinical decision making, and outcomes  
**Study type:** Multicenter, prospective, blinded, diagnostic accuracy study  
**Size:** 464

**Inclusion criteria:**Pts over the age of 18 y presenting to the ED with HF and who received treatment in the ED or hospital admission for HF were included.  
**Exclusion criteria:**Current MI or ACS with ST-segment deviation of ≥1 mm, renal failure requiring dialysis, or pts with a baseline BNP concentration of ≤100 pg/mL were excluded  
**Intervention:**Physicians were blinded to the actual BNP level and subsequent BNP measurements.  
**Comparator:**Comparison between severity of HF determined by physicians or BNP and outcomes  

**1st endpoint:**ED doctor’s intention to admit or discharge a pt had no influence on 90-d outcomes, while the BNP level was a strong predictor of 90-d outcome. The 90-d combined event rate (HF visits or admissions and mortality) in the group of pts admitted with BNP <200 pg/mL and >200 pg/mL was 9% and 29%, respectively (p=0.006).

- In pts presenting to the ED with HF, there is a disconnect between the perceived severity of HF by ED physicians and severity as determined by BNP levels. The BNP levels can predict future outcomes and thus may aid physicians in making triage decisions about whether to admit or discharge pts. Emerging clinical data will help further refine biomarker-guided outpatient therapeutic and monitoring strategies involving BNP.

### O'Connor et al. 2010 (26) 20185037

**Aim:** To identify high-risk HF pts at hospital discharge  
**Study type:** Predictive modeling using variables obtained during hospitalization in the ESCAPE trial  
**Size:** 423

**Inclusion criteria:**hospitalized with severe HF, LVEF ≤30%, SBP ≤125 mmHg.  
**Exclusion criteria:**creatinine >3.5 mg/dL, prior inotrope use  
**Derivation cohort:**ESCAPE trial, n=423  
**Validation cohort:**FIRST trial, n=471  

**1st endpoint:**  
- 6-mo mortality and death or rehospitalization rates (64%)  
- Multivariate discharge predictors of death included: BNP, per doubling (HR: 1.42), cardiac arrest or mechanical ventilation, yes/no (HR: 2.54), BUN, per 20 mg/dL increase (HR: 1.22) and sodium, per unit mEq/L increase (HR: 0.93)  
- A simplified discharge score discriminated mortality risk from 5% (score=0) to 94% (score=8).  
- Bootstrap validation demonstrated good internal validation for the model (c-index 0.78)  
- Limitations: ESCAPE represented pts with severe LV dysfunction and advanced symptoms (not the general population of acute HF) managed at experienced centers; exclusion of pts with characteristics

Study type: NR  
Size: 74 pts | Inclusion criteria:  
Pts diagnosed with acute HF in emergency department and who had follow-up evaluation for 6 & 12 mo after admission  
Follow up: 12 mo | 1° endpoints:   
- Percent reduction in NT-proBNP and its association with CV mortality  
Results:   
- The area under the ROC curve for % NT-proBNP reduction to predict CV death was 0.78 (95% CI: 0.66–0.90; p=0.002)  
- 30% NT-proBNP reduction percentage cutoff value had 75% accuracy for the identification of high-risk pts and was the only variable that was associated with CV death in multivariate analysis (OR: 4.4; 95% CI: 1.12–17.4; p=0.03).  
- Study relatively old and small |
| Verdiani et al. 2008 (28) 18545069 | Aim: To evaluate the prognostic significance of NT-proBNP % reduction during ADHF  
Study type: Prospective cohort  
Size: 120 pts | Inclusion criteria:  
Pts consecutively admitted with ADHF  
Follow up: 6 mo | 1° endpoint   
- Percent reduction in NT-proBNP and its association with CV mortality  
Results:   
- In ROC, the mean AUC for NT-ProBNP % reduction was 0.63 (95% CI: 0.51–0.75; p=0.04) for the composite endpoint (death or readmission), and 0.81 (95% CI: 0.65–0.97; p=0.01) for CV mortality at risk of events.  
- NT-ProBNP reduction percentage <30% was the best cut off for the identification of pts  
- Study relatively old and small |

| Richards et al. 2001 (37)         | **Study type:** Observational study within a randomized trial  
Inclusion criteria: Ischemic CM, EF<45%, chronic stable CHF, NYHA II-III or prior II–IV  
Exclusion criteria: Current NYHA IV, HR<50 bpm, BP<90 or >160/100, coronary event/procedure last 4 weeks, IDDM, CKD, hepatic/renal disease, sick sinus syndrome, 2nd or 3rd degree heart block, treatment with beta-blocker, beta-agonist or verapamil | Association of plasma N-BNP and adrenomedullin with mortality and HF events at 18 mo | - Above median proBNP increased risk of mortality (HR: 4.7; CI 2–10.9) and HF admission (HR: 4.7, CI: 2–10)  
- Above median adrenomedullin increased risk of mortality (HR 3.9,CI 1.8-8.7) and HF admission (HR 2.4, CI 1.3-4.5)  
- Associations persist in multivariable modeling  
- NT-proBNP and adrenomedullin levels are independently associated with outcome in pts with heart failure from an ischemic cardiomyopathy |
| Tang et al. 2003 (38)             | Study type: Retrospective, observational  
Inclusion criteria: Chronic systolic HF >3 mo duration, stable medical therapy, LVEF<50%, NYHA class I-III, followed in outpatient HF clinic at a single center who had BNP obtained at clinic visit  
Exclusion criteria: Congenital heart disease, cardiac transplant, primary valvular disease, active ischemia requiring urgent revascularization | Prevalence, clinical characteristics, and characteristics of a BNP<100 pg/mL in a HF clinic population | - 21% of symptomatic HF pts had BNP <100 pg/mL  
- Characteristics associated with this phenotype include younger age, female gender, nonischemic etiology, better preserved cardiac and renal function, less have atrial fibrillation  
- A sizeable minority (21%) of ambulatory pts with chronic HF have a BNP <100 pg/mL  
- This phenotype (HF with non-diagnostic BNP) is associated with identifiable clinical characteristics |
| Januzzi et al. 2008 (39)         | Study type: Review paper regarding utility of NT-proBNP testing for diagnosis or exclusion of HF in pts with acute HF  
Inclusion criteria: Studies using NT-proBNP assays used commercially  
Exclusion criteria: N/A | N/A | NT-proBNP testing can help with the diagnosis and triage of the patients with acute dyspnea. |

</table>
| Santaguida et al. 2014 (40) 25052418 | Study type: Systematic review | Size: 7 publications included | **Inclusion criteria:** Study assessing incremental value of BNP or NT-proBNP for predicting morbidity and mortality in acute decompensated HF | **1° endpoint:** BNP or NT-proBNP improved prognostic model performance for mortality as assessed by discrimination and or likelihood statistics | • Clinical heterogeneity precluded formal meta-analysis  
• 5 BNP publications consistently predicted all-cause mortality in short (3–6 mo) and long (9,12 mo) beyond base model but not all statistically significant  
• Two NT-proBNP publications both showed incremental value at 22 mo and 6.8 y with 1 being statistically significant  
• Studies of stable HF; natriuretic peptide could not be included in base model to allow assessment of incremental value |
| Hill et al. 2014 (41) 24957908 | Study type: Systematic review | Size: 76 publications included (37 BNP alone, 25 NT-proBNP alone, 14 both) | **Inclusion criteria:**  
• Age >18 y presenting to ED or urgent care center with signs/symptoms suggestive of acute HF  
• English language articles from 1989-2012  
• FDA-approved assays  
**Exclusion criteria:**  
• Studies with pts who had conditions that may impact NP levels (transplant, HCM, valvular) | **1° endpoint:** Test performance characteristics | • Both BNP and NT-proBNP had high sensitivity but low specificity  
• Overall strength of evidence for sensitivity and all decision cutpoints for both peptides was high; strength of evidence for specificity rated as moderate.  
• Both BNP and NT-proBNP performed well to rule out, but less well to rule in, for the diagnosis of heart failure among patients presenting to the ED or urgent care centers.  
• BNP pooled sensitivity=95%, 95% CI: 93–97%, specificity 67% (58–75%)  
• NT-proBNP pooled sensitivity 91% (95% CI: 88–93), specificity 67% (50–80%) |
| Zaphiriou et al. 2005 (42) 15921792 | Study type: Diagnostic accuracy study (observational) | Size: 306 pts | **Inclusion criteria:** Pts with new symptoms suggestive of HF referred by GP to rapid access HF clinics at 5 centers in UK between 201 and 2003 | **1° endpoint:** Sensitivity, specificity, PPV, NPV, LR, AUC for diagnosis of HF | • 2 of 5 sites withdrew after recruiting 18 and 14 pts  
• Both BNP and NT-proBNP are useful for ruling out HF in pts presenting to PCP with possible HF symptoms  
• 104 (34%) of pts had HF |

</table>
### Aim:
To derive and validate a model for acute HF mortality applicable in the ED.

**Study type:** Multicenter Registry analysis

**Inclusion criteria:** Population-based random sample of 12,591 pts presenting to the ED from 2004 to 2007

**Exclusion criteria:** No lab availability

**Size:** 12,591

**1° endpoint:** Death within 7 d of presentation

**Results:**
- Mortality risk increased with higher triage heart rate (OR: 1.15; [95% CI: 1.03–1.30] per 10 beats/min) and creatinine concentration (OR: 1.35; [CI: 1.14–1.60] per 1 mg/dL [88.4 micro mol/L]), and lower triage SBP (OR: 1.52 [CI: 1.31–1.77] per 20 mm Hg) and initial oxygen saturation (OR, 1.16 [CI: 1.01–1.33] per 5%).

- **A multivariate index comprising routinely collected variables stratified mortality risk with high discrimination in a broad group of pts with acute HF presenting to the ED.**

---

### Dhaliwal et al. 2009

**Aim:**
To compare the relationship between absolute and relative changes in BNP with future clinical events, and whether serial BNP measurements add prognostic information in pts treated for decompensated HF

**Study type:** Retrospective registry analysis

**Inclusion criteria:** Pts hospitalized for acute decompensated HF by Framingham criteria

**Exclusion criteria:** Renal failure, severe lung disease, acute coronary syndrome

**Size:** 203

**1° endpoint:** For the combined end point of total mortality or readmission for HF

**Results:**
- Increasing tertiles of BNP levels after treatment had a hazard ratio of 1.4 (1.1–1.7, p<0.01) and increasing tertiles of percent reduction in BNP, had a HR:0.7 (0.6–0.9; p=0.005), respectively, for the combined end point of total mortality or readmission for HF
- Follow-up BNP performed better than did baseline BNP or percent reduction in BNP.
- More BNP measurements other than the follow-up BNP did not improve the fit of the model further.

- **Both lower absolute BNP levels and greater percentage reduction in BNP with treatment of decompensated HF are associated with better event-free survival.**
- **Advocating a threshold BNP to which pts should be treated may not be possible given that high BNP levels tend not to decrease to levels associated with better outcomes during the short period of treatment.**
- **More BNP measurements do not add prognostic information beyond that provided by a single BNP level after treatment.**

---

### Alonso-Martinez et al. 2002

**Aim:**
To determine usefulness of CRP in predicting need for readmission in HF

**Inclusion criteria:** Intervention group: admission with HF; control group: admission with syncope

**1° endpoint:** 18-mo HF readmission

- CRP levels were higher in pts with HF compared to syncope (3.94 vs. 0.84, p=0.0007)

- **Multivariate predictors of readmission were CRP levels, NYHA class and plasma K on discharge**
- **Limitation: small, single-center**

</table>

**Dieplinger et al. 2010 (55)**

**Aim:** To evaluate the prognostic value of established and novel biomarkers in pts with acute dyspnea

**Study type:** Observational

**Size:** 251

**Inclusion criteria:** Pts presenting to ED with acute dyspnea

**Exclusion criteria:** STEMI, NSTEMI or ACS troponin pos.

**Biomarkers:** BNP, MR-proANP, MR-proADM, copeptin, C-terminal pro-ET-1, soluble ST2, chromogranin A (CgA), adiponectin, proguanylin, prouroguanylin

**Safety endpoint:** All-cause mortality at 1 y

- 25% died within 1 y
- At baseline, decedents (n=62) had higher median plasma concentrations of all 10 biomarkers than survivors (n=189)
- In multivariate model, only MR-proANP (RR: 1.6), ST2 (RR: 1.7) and CgA (RR: 1.5) were independent predictors of death
- Low systolic BP and advanced age were also independent predictors of 1-y mortality
- Limitations: post-hoc analysis; subgroup (87 of 251) had dyspnea due to acute HF alone; single-center, majority men (94%)

**Ilva et al. 2008 (56)**

**Aim:** To evaluate prevalence and prognostic significance of elevated cTnI and cTnT in acute HF

**Study type:** Observational substudy

**Size:** 364

**Inclusion criteria:** Hospitalized with acute HF

**Exclusion criteria:** ACS pts; missing sample for cardiac TnI/TnT

**Biomarkers on admission and 48 hours:** cTnT, cTnI, cystatin C, NT-proBNP

**Safety endpoint:** 6-mo mortality

- 51% of pts had +cTnI and 30% had +cTnT
- 6-mo all-cause mortality was 18.7%
- Both cTnI (OR: 2.0; 95% CI: 1.2–3.5) and cTnT (OR: 2.6; 95% CI: 1.5–4.4) were associated with adverse outcome in pts with previous, but no de novo HF
- On multivariable analysis, cystatin C (OR: 6.3; 95% CI: 3.2–13), logNT-proBNP (OR: 1.4; 95% CI: 1.0–1.8) and SBP on admission (10 mm Hg increase; OR: 0.9; 95% CI: 0.8–0.9) were independent risk predictors, whereas troponins were not
- Mortality was proportional to troponin release
- Limitations: exclusion of pts with ACS was based on clinician judgment; cut-off values for troponins was based on 2000 ESC/ACC guidelines

**Januzzi et al. 2007 (57)**

**Aim:** To examine the value of measuring ST2 in pts

**Study type:** Observational substudy

**Size:** 76

**Inclusion criteria:** Pts presenting to ED with acute dyspnea

**Exclusion criteria:** Clear cause for elevated CRP (e.g., inflammation, infection)

**Safety endpoint:** death at 1 y

- ST2 levels were significantly higher in pts with ST2 levels were higher in pts with HF/EF (0.67 ng/ml; IQR 0.31–1.50) vs. HFpEF (0.42 ng/ml; IQR 0.22–

</table>

**Study type:** Observational

**Size:** 593 (pts with acute HF 209, other causes of acute dyspnea 384)

**Exclusion criteria:** Not reported

**ST2 levels** were significantly higher in decedents than survivors (1.03 vs. 0.18 ng/ml; p<0.001).

In multivariable analysis, ST2 ≥0.20 ng/ml strongly predicted death at 1 y.

**1-y mortality was 15.7%**

**BT2 levels were significantly higher in deceased than survivors (1.03 vs. 0.18 ng/ml; p<0.001).**

**In multivariable analysis, ST2 ≥0.20 ng/ml strongly predicted death at 1 y.**

**Biomarkers:** ST2, troponin T, NT-proBNP, CRP

**Limitations:** single-center study; biologic role of ST2 in acute HF poorly understood.

---

**Aim:** To determine whether risk of mortality associated with ST2 differs in pts with acute HFrEF vs. HFrEF.

**Inclusion criteria:** Acute HF

**Exclusion criteria:** N/A

**ST2 levels** were higher among deceased than survivors (median 0.80 ng/ml vs.0.38 ng/ml; p<0.001); and this pattern was true for HFrEF and HFpEF. On multivariate analysis, elevated ST2 levels were associated with greater risk of 1-y mortality for HFpEF (HR: 1.41; 95% CI: 1.14–1.76) than HFrEF (HR: 1.20; 95% CI: 1.10–1.32).

---

**Aim:** To examine patient-specific characteristic of ST2 in pts with acute HF.

**Inclusion criteria:** Acute HF

**Exclusion criteria:** N/A

**ST2 levels** correlated with severity of HF (p<0.001), LVEF and creatinine clearance.

**ST2 levels** correlated with BNP, NT-proBNP and CRP.

In a multivariable model, ST2 remained a predictor of mortality (HR: 2.04; 95% CI: 1.30–3.24).

---

**Aim:** To determine whether risk of mortality associated with ST2 differs in pts with acute HFrEF vs. HFrEF.

**Inclusion criteria:** Acute HF

**Exclusion criteria:** N/A

**Aim:** To determine the relationship between galectin-3 and cardiac structure and function in pts with acute dyspnea

**Study type:** Observational

**Size:** 115

**Inclusion criteria:** PT presenting to ED with acute dyspnea, detailed echo exams during admission

**Exclusion criteria:** N/A

**Biomarkers:** galectin-3, NT-proBNP

**1° endpoint:**
- Association between galectin-3 and echo and clinical indices
- Higher levels of galectin-3 associated with older age, poorer renal function, and higher NT-proBNP
- Significant relationship between galectin-3 and poorer RV function, higher RV systolic pressure and more severe MR and TR
- Galectin-3 levels higher in pts who died at 1 and 4 y
- In multivariate analysis, galectin-3 remained a significant predictor of 4-y mortality independent to echocardiographic markers of risk
- Limitations: delay between collection of biomarkers and echocardiograms; small, single-center cohort

### LCZ696 with enalapril in HF

**Study type:** RCT  
**Size:** 8,442

**Exclusion criteria:**  
- Symptomatic hypotension, SBP <95 mm Hg  
- eGFR <30 mL/min/1.73m² of body surface area  
- Serum K level >5.2 mmol/L  
- Angioedema history  
- Unacceptable side effects of ACE inhibitors or ARBs

**Comparator:** Enalapril (4,212) target 10 mg BID (mean 18.9±3.4 mg daily)

**Hospitalization for HF**
- Results: Composite less in LCZ696 group vs. enalapril, 914 (21.8%) vs. 1,117 (26.5%), HR: 0.80 (95% CI: 0.73–0.87; p<0.001)
- Less HF hospitalizations in LCZ696 arm (537 vs. 658), HR: 0.79 (95% CI: 0.71–0.89; p<0.001)
- Less death from any cause in LCZ696 arm (711 vs. 835), HR: 0.84 (95% CI: 0.76–0.93; p<0.001)
- The change from baseline to 8 mo in the score on the KCCQ in LCZ696 arm (2.99 points reduction vs. 4.63 points), HR: 1.64 (95% CI: 0.63–2.65; p=0.001)
- No difference in new onset of AF (84 vs. 83; p=0.84)
- No difference in protocol defined decline in renal function, HR: 0.86 (95% CI: 0.65–1.13; p=0.28)
- More symptomatic hypotension (14% vs. 9.2%; p<0.001)
- No difference in angioedema, 19 vs. 10 (p=0.13)

| (62) 25176015 | pg/mL, hospitalized for HF ≤12 mo (≥BNP100 pg/mL), on ACE inhibitors or ARBs ≥4 wk before screening, required to take stable dose of beta blockers and an ACE inhibitor (or ARB) equal to 10 mg of enalapril. Prior to randomization pts were required to complete 2 wk each of enalapril 10 mg BID and LCZ 100 BID. | 375±71 mg daily | 2017 Heart Failure Focused Update Data Supplement | Search Terms and Date: 3 trials identified by chairs in December 2015. |

### Mineralocorticoids Antagonist Trials

#### EMPHASIS subgroup analysis

**Aim:** Investigate the safety and efficacy of eplerenone in pts at high risk for hyperkalemia

**Study Type:** Prespecified subgroup analysis of RCT

**Size:** 2,737

**Inclusion Criteria:** Pts enrolled in EMPHASIS at high risk for hyperkalemia of worsening renal function (>75 y, DM, eGFR <60, or SBP <123)

**Exclusion Criteria:** eGFR<30

**Intervention:** Randomization to eplerenone

**Comparator:** Placebo

**1° endpoint:**
- Efficacy: Hospitalization for HF or worsening renal failure. **Safety:** K >5.5, >6.0, <3.5, hospitalization for significant hyperkalemia, hospitalization for worsening renal function

**Results:** Efficacy: reduced composite endpoint. Safety: increased risk of K+ >5.5 mmol/L, hospitalization for hyperkalemia or discontinuation of study medication due to adverse events. No differences from the main trial results in the high-risk subgroups. K >5.5 was increased in the whole cohort and the subgroups, but K >6.0, clinically significant hyperkalemia, and change in eGFR were not substantially higher.

- The beneficial effects of eplerenone were maintained in the high-risk subgroups.

#### RALES

**Aim:** To investigate the effect of spironolactone on mortality and morbidity in pts with severe HF.

**Study Type:**

**Inclusion Criteria:** NYHA class III, IV; HF≤6 mo, Left EF≤35%, On ACE inhibitors, loop diuretic. Digitalis and vasodilators allowed.

**Exclusion Criteria:** 1° operable VHD (other than

**Intervention:** Spironolactone 25 mg daily (822)

**Comparator:** Placebo (841)

**1° endpoint:**
- Death from all causes

**Results:**
- Placebo vs. Spironolactone group (46% vs. 35%; RR: 0.70; 95% CI: 0.60–0.82; p<0.001)
- Trial stopped early due to favorable results at 24 mo.

- Reduction in death from cardiac causes and Hospitalization for cardiac causes (p<0.001)
- Improvement in NYHA class (p<0.001)
- No clinically important safety concerns for electrolytes. Gynecomastia/breast pain more frequent in the spironolactone

| IMPRESS Rouleau et al. 2000 (68) 10968433 | Aim: Determine if inhibition of neutral endopeptidase and ACE with the vasopeptidase inhibitor omapatrilat is better than ACE inhibition alone with lisinopril  
Study type: Double blind RCT  
Size: 573 pts | Inclusion criteria:  
- Informed consent  
- Age ≥18  
- Stable (>3 mo) symptomatic HF (NYHA class II–IV HF)  
- Decreased LVEF <40  
- ≥4 wk dose of ACE inhibitors  
- Seated SBP ≥90 mm Hg  
Exclusion criteria:  
- Uncontrolled hypertension  
- Acute coronary events within 3 mo  
- Revascularization within 3 mo  
- Serum potassium <3.5 or >5.3 mmol/L  
- Creatinine >221 mmol/L  
- Transaminases >2 upper limit of normal  
- Leucocytes <3.0x10^9/L, neutrophils <1.5x10^9/L, or platelets <120x10^9/L | Intervention: Omapatrilat (289) target dose 40 mg daily  
Comparator: Lisinopril (284) target dose 20 mg daily | 1° endpoint: Change in exercise duration from baseline to wk 12  
Results: Similar exercise duration at 12 wk (p=0.45) | 2° endpoint:  
- No difference in combined endpoint of death and admission for worsening HF (p=0.52)  
- Combined endpoint of death and comorbidity for worsening HF was better for omapatrilat HR: 0.52 (95% CI: 0.28–0.96; p=0.035)  
- Angioedema occurred in no pts taking omapatrilat vs. 1 taking enalapril  
Comments: Vasopeptidase inhibitor omapatrilat did not improve exercise tolerance compared with ACE inhibitor lisinopril |
### OVERTURE

**Packer et al. 2002**

- **Aim:** Determine dual ACE and NEP inhibitors provides greater benefit in pts with HF than ACE inhibitors alone
- **Study type:** Double blind RCT
- **Size:** 5,770 pts

**Inclusion criteria:**
- NYHA class II–IV HF due to non/ischemic cardiomyopathy for ≥2 mo, or
- LVEF ≤30% and hospitalized for HF within 12 mo

**Exclusion criteria:**
- Surgically correctable or reversible cause of HF
- Likely to receive cardiac transplant or left ventricular assist device
- Severe 1° pulmonary, renal, or hepatic disease
- Hx of intolerance to ACE inhibitors
- ACS within 1 mo
- Coronary revascularization or an acute cerebral ischemic event within 3 mo
- Hx of ventricular tachycardia, ventricular fibrillation, or sudden death who did not have an ICD placed and had not fired within 2 mo
- Hx or hospitalization or intravenous therapy for HF within 48 h
- IV positive inotropic agent within 2 wk
- SBP >180 or <90 mm Hg
- Heart rate >130 bpm
- Serum creatinine >2.5 mg/dL
- Serum potassium <3.5 or >5.2 mmol/L

**Intervention:**
- Omapatrilat (2,886), target dose 40 mg daily achieved 82.5%

**Comparator:**
- Enalapril (2,884) target dose 10 mg BID achieved 86.4%

1° endpoint: Combined risk of death or hospitalization for HF requiring IV treatment

**Results:**
- No significant difference HR: 0.94 (95% CI: 0.86–1.03; p=0.187)
- Omapatrilat reduced risk of death and hospitalization for chronic HF HR: 0.89 (95% CI: 0.82–0.98; p=0.012). For this analysis, pts were treated with intensification of oral medications.
- More frequent angioedema with omapatrilat (0.8% vs. 0.5%)

### OCTAVE

**Kostis et al. 2004**

- **Aim:** Compare safety and efficacy of dual ACE and NEP inhibitors to ACE inhibitors alone
- **Study type:** Double blind RCT
- **Size:**

**Inclusion criteria:**
- Age ≥18
- 3 separate BP criteria for 3 groups: Group 1 untreated hypertension (SBP ≥140 mm Hg or DBP ≥90 mm Hg); Group 2 hypertension and persistent mild hypertension (trough SBP 140–159 mm Hg and DBP <100 mm Hg, or trough DBP 90–99 mm Hg and SBP <160 mm Hg);

**Intervention:**
- Omapatrilat target dose 80 mg daily

**Comparator:**
- Enalapril target dose 40 mg daily

1° endpoints:
- Reduction in SBP at wk 8
- Need for new adjunctive antihypertensive therapy by wk 24

2° endpoints:
- Reduction in DBP at wk 8
- Reduction in SBP and DBP at wk 24
- BP control (SBP <140 mm Hg and DBP <90 mm Hg) at wk 8 and 24
### Exclusion criteria:
- Contraindication to therapy with ACE inhibitors or angiotensin II receptor antagonists
- Hx of angioedema, anaphylaxis, drug-induced or chronic urticarial, or multiple drug sensitivities
- Recent hospitalization for MI, unstable angina, stroke, TIA or COPD
- Recent treatment for malignancy, chronic renal disease 2° to autoimmune disease, or end-stage renal disease of any etiology
- Hypertensive pts treated with ACE inhibitors whose BP placed them in study group 3

- Greater reductions in BP in omapatrilat within each study (p<0.001)
- Overall mean reduction in SBP ≥3.6 mm Hg
- Larger reductions in BP in black pts with omapatrilat than with enalapril. But overall reduction smaller with both drugs than in other subgroups.
- Adverse events, serious adverse events, and deaths were the same for omapatrilat and enalapril
- More angioedema with omapatrilat (2.17% vs. 0.68%) and more angioedema in blacks with omapatrilat (5.54% vs. 1.62%) and current smokers (3.93% vs. 0.81%)

- Hospitalization for worsening HF: ivabradine better. 16% vs 21%, HR: 0.74 (95% CI: 0.66–0.83; p<0.001)
- Death from HF: ivabradine better. 3% vs. 5%; HF: 0.74 (0.58–0.94); p=0.014

- Composite of CV death or hospital admission for worsening HF among those receiving at least 50% of target beta blocker dose at time of randomization. All cause death; any CV death; HF hospitalization; all-cause hospitalization; any CV hospitalization; death from HF; composite of CV death HF hospitalization, nonfatal MI.
- No difference in all-cause mortality or CV mortality
- Ivabradine better for all-cause hospitalization, HF hospitalization, CV hospitalization, and composite 2° endpoint
- Analyzed as time to first event. Median follow-up of 22.9 mo
- In subgroup analysis, effect limited to those with higher baseline heart rate (≥77 bpm)
- Use of devices was low (CRT in 1% and ICD in 4%)
- Mean age 61 y
- When added to GDEM, including beta blocker at optimal dose, ivabradine reduced adverse events, driven largely by HF mortality or HF hospitalization

#### Adverse Effects:
- 1% withdrew due to bradycardia (p<0.001)
- Phosphenes 3% (p=0.001)
- Comparable across age groups
- AF - ivabradine 9% vs. placebo 8% (p=0.012)

### SIGNIFY

### SHEP HF Results

**Kostis et al. 1997**  
**Study type:** RCT  
**Size:** 4,736  
**Inclusion criteria:** Age > 60, SBP 160–219, DBP < 90  
**Exclusion criteria:** Recent MI or CABG, pts with DM, stroke, AF  
**Intervention:** Antihypertensive therapy: step 1, chlorthalidone, step 2, atenolol (2,365)  
**Comparator:** Placebo (2,371)  
**1° endpoint:**  
- Incident HF  
- Active treatment decreased BP from mean of 170/77 to mean of 159/70 and decreased HF events from 105 (4.4%) with placebo to 55 (2.3%) RR: 0.51 (95% CI: 0.37–0.71, p<0.001) at 4.5 y  
- 1° results of SHEP showed decreased stroke risk with active treatment 149 (8.2%) with placebo to 96 (5.4%) RR: 0.64 (95% CI: 0.49–0.82, p=0.003) at 4.5 y  
- LV function was not measured

### CHARM-Preserved

**Yusuf et al. 2003**  
**Study type:** RCT  
**Size:** 3,023  
**Inclusion criteria:** HF pts in NYHA class II-IV with EF > 40%  
**Exclusion criteria:** Creatinine > 265 μmol/L (3.0 mg/dL), potassium > 5.5 mmol/L, MI, stroke, or open-heart surgery in the previous 4 wk  
**Intervention:** Candesartan (1,514)  
**Comparator:** Placebo (1,509)  
**1° endpoint:**  
- CV death or admission for HF.  
- No difference for candesartan 333 (22%) vs. placebo 366 (24%) at 3.5 y, HR: 0.92; 95% CI: 0.70–1.21; p=0.5.  
- No differences for 2° endpoints except for covariate adjusted risk of HF admission HR: 0.86 (95% CI: 0.74–1.00; p=0.051).  
- HF hospitalization lower at 1 y with perindopril: 34 events (8.0%) vs. placebo 53 (12.4%), HR: 0.63; 95% CI: 0.41–0.97; p=0.033.  
- Limitations: Some pts may have had previous EF < 40%.

### PEP-CHF

**Cleland et al. 2003**  
**Study type:** RCT  
**Size:** 3,023  
**Inclusion criteria:** Age ≥ 70, Rx with diuretics for clinical diagnosis of HF, echo criteria for diastolic dysfunction  
**Exclusion criteria:**  
- All-cause mortality or admission for HF.  
- No difference for perinopril 107 (25.1%) vs. placebo 131 (23.6%) at 3 y, HR: 0.92; 95% CI: 0.70–1.21; p=0.5.  
- FF hospitalization lower at 1 y with perindopril: 34 events (8.0%) vs. placebo 53 (12.4%), HR: 0.63; 95% CI: 0.41–0.97; p=0.033.  
- Limitations: Many pts withdrew (40% by 18 mo), often to take open-label ACE inhibitors (36% by study end).

**Inclusion criteria:**
- Symptomatic HF, Age ≥50y, LVEF ≥45% stratified according to:
  - HF Hospitalization within past y
  - Elevated NPs

**Exclusion criteria:**
- Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL), systemic illness with life expectancy <3 y. Specific co-existing conditions, meds, and acute events

**Intervention:**
- Spironolactone (1,722)

**Comparator:**
- Placebo (1,723)

**1st endpoint and results:**
- Composite of CV mortality, HF hospitalization, or aborted cardiac arrest.
- No difference with spironolactone vs. placebo 320 (18.6%) vs. 351 (20.4%), HR: 0.83; 95% CI: 0.69–0.99; p=0.04
- Increased hyperkalemia (18.7% vs. 9.1%), decreased hypokalemia (16.2% vs. 22.9%) and more doubling of creatinine (10.2% vs. 7.0%) with spironolactone

**double-blind**
- **Size:** 216
- **PCWP**
- **Exclusion criteria:**
  - Systolic BP <110mm Hg and >180 mm Hg, MMI or revascularization within 60 d, eGFR <20 mL/min

**IQR -0.70–1.0)**
- More worsening of renal function in sildenafil group (p=0.047)

**chronotropic incompetence in study population.**
### TOPCAT Regional Analysis

**Pfeffer et al. 2015 (84) 25406305**

Post-hoc analysis that captures differences in outcomes by geography

| **Aim:** | To assess regional differences in the effects of spironolactone in pts with HFrEF. |
| **Study type:** | RCT |
| **Size:** | 3,445 |
| **Inclusion criteria:** | Symptomatic HF, Age ≥50y, LVEF ≥45% stratified according to: HF Hospitalization within past y, Elevated NPs |
| **Exclusion criteria:** | Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL), systemic illness with life expectancy <3 y. Specific co-existing conditions, meds, and acute events |
| **Intervention:** | Spironolactone (1,722) |
| **Comparator:** | Placebo (1,723) |
| **1° endpoint and results:** | Composite of CV mortality, HF hospitalization, or aborted cardiac arrest across regions. 1° outcome event rates with spironolactone and placebo 10.4/100 pt y and 12.6/100 pt y in the Americas and 2.5/100 pt y and 2.3/100 pt y in Russia/Georgia. HR spironolactone vs. placebo 0.82; 95% CI: 0.69–0.98; p=0.026) in the Americas and 1.10 95% CI: 0.79–1.51; p=0.12) in Russia/Georgia. |
| **Intervention:** | Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001) |
| **Limitations:** | post-hoc analysis |

---

### Chen et al. 2015 (85) 25598008

| **Aim:** | To assess effects of MRAs in pts with HFrEF. |
| **Study type:** | Meta-analysis |
| **Size:** | 14 RCTs with 6,428 pts |
| **Inclusion criteria:** | Prospective, RCTs that enrolled adult pts with LVEF ≥40% (including post-MI and those with symptomatic or asymptomatic HF) with a study duration of ≥24 mo that assessed at least 1 clinical outcome of interest. |
| **Intervention:** | MRAs (3,249) |
| **Comparator:** | Placebo (2,861) Or standard therapy (301) Or active comparator (31) |
| **1° endpoint and results:** | All-cause mortality and HF hospitalization: No difference in all-cause mortality (RR: MRAs vs. placebo 0.90; 95% CI: 0.78–1.04; p=0.17) Reduced risk of HF hospitalization (RR: MRA vs. placebo 0.83; 95% CI: 0.70–0.98; p=0.03) |
| **1° Safety endpoint:** | More hyperkalemia with MRAs (12.2% vs. 6.2%, p<0.001) |
| **Limitations:** | discrepancies in definitions of HFrEF in different trials; heterogeneity of trial outcomes and their assessment, including follow-up duration; 1° outcome results driven by |

<td>PARAMOUNT Solomon et al. 2012 (61) 22932717</td>
<td><strong>Aim:</strong> To address safety and efficacy of LCZ696 in pts with HFrEF.</td>
<td><strong>Inclusion criteria:</strong> Pts ≥40 y of age, LVEF ≥45%, NYHA class II-III HF, NT-pro BNP &gt;400 pg/mL</td>
<td><strong>Intervention:</strong> LCZ696 (149)</td>
<td><strong>Comparator:</strong> Valsartan (152)</td>
<td><strong>1° endpoint:</strong> Change in BNP at 12 wk Greater reduction with LCZ696 (ratio of change compared to valsartan 0.77; 95% CI: 0.64–0.92; p=0.001)</td>
</tr>
</tbody>
</table>

**Study Limitations:**
- Previous EF <45%, isolated right HF, noncardiac dyspnea, CAD or CVD needed revascularization <3 mo
- Right HF due to pulmonary disease, dyspnea due to noncardiac causes, valvular/myocardial disease, CAD or CVD needing revascularization within 3 mo of screening.

**Adverse Events:**
- 15% in LCZ676 group and 20% in valsartan group (p=NS)
- Improvement in NYHA class at 36 wk in LCZ676 group compared to valsartan.
- Reduction of LA size at 36 wk in LCZ676 group compared to valsartan.
- BNP levels higher than in other HFrEF trials, perhaps because this was an entry criterion.

Date: Some studies added by chairs in December 2015, others added by the writing committee.

<tbody>
<tr>
<td>Xie et al. 2016 (89) 26559744</td>
<td>Aim: To assess the efficacy and safety of intensive BP lowering strategies. <strong>Study Type:</strong> SR and meta-analysis <strong>Size:</strong> 19 trials with 44,989 pts; 3.8 y of follow-up. <strong>Inclusion Criteria:</strong> RCTs with different BP targets or different BP changes between more vs. less intense therapy with at least 6 mo follow-up. <strong>Exclusion Criteria:</strong> Trials that did not assess a different target or relevant outcome.</td>
<td>5 RCTs (6,960 pts) enrolled only pts with DM and 6 trials (2,809 pts) specifically recruited pts with CKD.</td>
<td>1st Outcomes: Major CV events, defined as MI, stroke, HF or CV death, separately and combined; nonvascular and all-cause mortality; ESRD; and adverse events; new onset microalbuminuria/macroalbuminuria or change from micro- to macroalbuminuria and retinopathy in pts with DM. Results: Pts in the more intensive BP-lowering treatment group had mean BP 133/76 mm Hg compared with 140/81 mm Hg in the less intensive group. Intensive BP-lowering treatment achieved RR reductions for major CV events: 14% (95% CI: 4, 22), MI: 13% (95% CI: 0, 24), stroke: 22% (95% CI: 10, 32), albuminuria: 10% (95% CI: 3, 16), and retinopathy progression: 19% (95% CI: 0–34). However, more</td>
<td>Study Limitations: Only 6,960 pts with DM were included in the total study size of 44,989 pts. Conclusions: The absolute CV benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease or DM. However, only 6,960 of the 44,989 pts had DM and no subanalysis for DM was provided; however, the outcome benefits were qualitatively most striking for pts with DM, CKD and/or vascular disease.</td>
<td></td>

</tbody>
</table>
intensive treatment had no clear effects on HF: RR: 15% (95% CI: -11, 34), CV death: 9% (-11, 26), total mortality: 9% (95% CI: -3, 19), or ESRD: 10% (95% CI: -6, 23). The reduction in major CV events was consistent across pt groups, and additional BP lowering had a clear benefit even in pts with SBP <140 mm Hg. The absolute benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease, or DM. Serious adverse events associated with BP lowering were only reported by 6 trials and had an event rate of 1.2% per y in intensive BP lowering group pts, compared with 0.9% in the less intensive treatment group (RR: 1.35 (95% CI: 0.93, 1.97)). Severe hypotension was more frequent in the more intensive treatment regimen (RR: 2.68 (95% CI: 1.21, 5.89), p=0.015), but the absolute excess was small (0.3% vs. 0.1% per pt-y for the duration of follow-up).

### SPRINT

**Aim:** To test the effectiveness of a goal SBP <120 mm Hg vs. a goal SBP <140 mm Hg for the prevention of CVD in pts with SBP ≥130 mm Hg at BL.

**Study type:**

**Inclusion criteria:**
- SBP ≥130 mm Hg, with upper limit varying as number of pre-trial BP-lowering meds increased.
- Age ≥50 y
- Presence of at least 1:
  - Clinical or subclinical CVD

**Intervention:**
- Intensive BP lowering treatment to goal SBP <120 mm Hg (4,678)

**Comparison:**
- Standard BP lowering treatment to goal SBP <140 mm Hg (4,678)
- Net treatment difference: ~3 drugs (2.8) on average vs. 2 drugs (1.8) on

**1° Endpoint:**
- Composite of MI, non-MI ACS, stroke, ADHF, CV death; HR: 0.75 (95% CI: 0.64, 0.89)
- Lower BP target reduced composite outcome 243 pts (1.65%/y) vs. higher target 319 (2.19%/y), HR: 0.75; 95% CI: 0.64–0.89; p<.001) and death: lower target 155 vs. 201, HR: 0.73; 95% CI: 0.60–0.90;

**Summary:**
- More intensive SBP lowering to a goal of <120 mm Hg with achieved mean of ~121 mm Hg resulted in less CVD and lower total mortality over 3.26 y in comparison with a goal SBP <140 mm Hg and achieved SBP of ~135 mm Hg.
- There were small increases in some expected SAEs. Perhaps unexpected, a sizable increase...

### SPRINT Senior Williamson et al. 2016 (91) 27195814

**Aim:** Intensive SBP goal (<120 mmHg) vs standard (SBP goal <140)

**Study Type:** RCT

**Size:** 2,636

30% met criteria for being classified as ambulatory frail

**Mean follow-up:** 3.1 y

**Inclusion:** Men and women age 75+; mean age 79.8 y; 38% women; 17% black, 74% Caucasian; Exclusions: Nursing home residents; diabetes, Stroke, symptomatic HF in past 6 mo or EF <35%, dx or treatment of dementia, unintentional wt loss >10% in past 5 mo. SBP<110 after standing 1 min, expected survival <3y

**Intervention:** Medications and dietary advice to achieve SBP of <120 mm Hg

**Comparator:** Medications and dietary advice to achieve SBP of <140 mm Hg

**Achieved SBP:**
- Intensive= 123.4 mm Hg
- Standard= 134.8 mm Hg

**1 endpoint:** Composite CVD outcome (AMI, non-MI ACS, Stroke, HF, CVD death).

**Results:**
- 102 events in the intensive treatment group vs 148 events in the standard treatment group; HR: 0.66; 95%CI: 0.51–0.85
- and all-cause mortality (73 deaths vs. 107 deaths, respectively; HR: 0.67; 95%CI: 0.49–0.91)

No significant difference in falls, orthostatic hypotension, or overall SAEs.

**1^ endpoint and results:**
- Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001)

**Limitations:**
- Does not apply to nursing home patients or those with dementia

**Conclusions:** Intensive SBP is safe and effective for lowering CVD events and total mortality in persons age 75 and older

### TOPCAT Regional Analysis Pfeffer et al. 2015 (84) 25406305

Post-hoc analysis that captures differences in outcomes by geography

**Aim:** To assess regional differences in the effects of spironolactone in pts with HFpEF.

**Study Type:** RCT

**Size:** 3,445

**Inclusion criteria:**
- Symptomatic HF, Age ≥50y, LVEF ≥45% stratified according to
- HF Hospitalization within past y
- Elevated NPs

**Exclusion criteria:**
- Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL)), systemic illness with life expectancy <3 y. Specific co-existing

**Intervention:** Spironolactone (1,722)

**Comparator:** Placebo (1,723)

**1^ endpoint and results:**
- Composite of CV mortality, HF hospitalization, or aborted cardiac arrest across regions.
- 1^ outcome events in 522 (29.5%) pts in the Americas and 149 (8.9%) in Russia/Georgia. 1^ outcome event rates with spironolactone and placebo 10.4/100 pt y and 12.6/100 pt y in the Americas and 2.5/100 pt y and 2.3/100 pt y in Russia/Georgia. HR spironolactone vs. placebo 0.82; 95% CI: 0.69–0.98; p=0.026) in the Americas and 1.10 95% CI: 0.79–1.51; p=0.12) in Russia/Georgia.

**Limitations:**
- Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001)

**Conclusions:**
- Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001)
**Study type:** Meta-analysis of use of BP lowering drugs in prevention of CVD from 147 randomized trials

**Size:** Of 147 randomized trials of 464,000 pts, 37 trials of beta blockers in CAD included 38,892 pts, and 37 trials of other antihypertensive drugs in CAD included 85,395 pts

**Inclusion criteria:**
The database search used Medline (1966-Dec. 2007 in any language) to identify randomized trials of BP lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles.

**Exclusion criteria:**
Trials were excluded if there were <5 CAD events and strokes or if treatment duration was <6 mo.

**1st endpoint:**
CAD events; stroke

**Results:**
In 37 trials of pts with a history of CAD, beta blockers reduced CAD events 29% (95% CI: 22%–34%). In 27 trials in which beta blockers were used after acute MI, beta blockers reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which beta blockers were used after long term CAD, beta blockers insignificantly reduced CAD events 13%. In 7 trials, beta blockers reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACE inhibitors, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 28%–47%) in 10 trials.

• With the exception of the extra protective effect of beta blockers given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP.

OSA among nationwide AF population;

1) Determine whether OSA is associated with:
   a) Worse outcomes;
   b) Arrhythmic AF progression; &

2) Determine whether OSA is associated with:
   a) Higher risk of:
      o Hospitalization (43 vs 35 events/100 patient-years among patients without OSA [adjusted hazard ratio (HR), 1.12; 95% confidence interval (CI), 1.03-1.22; p=.0078]
   b) No higher risk of:
      o Death (HR, 0.94; 95% CI, 0.77-1.15; p=.54);
      o Composite of CV death, stroke/non–central nervous system embolism, TIA, or MI (HR, 1.07; 95% CI, 0.85-1.34; p=.57);
      o First major bleeding (HR, 1.18; 95% CI, 0.96-1.46; p=.11)

3) Determine whether CPAP treatment is associated with outcomes in patients with AF & OSA.

Study type:• Prospective descriptive, correlational / comparative, time-series design• Data collection at enrollment & 6-month intervals for minimum of 2 years

Size: Nationally representative

Exclusion criteria:
• Life expectancy of <6 months or AF secondary to reversible conditions

Multicenter, ambulatory-based registry

deadth, stroke/non–central nervous system embolism, TIA, or MI;
• First major bleed within 2 years of baseline enrollment in registry

Results:
Frequency of diagnosed OSA among nationwide AF population
• 18% (n =1,841)

OSA associations w/ outcomes
• Higher risk of:
  o Hospitalization (43 vs 35 events/100 patient-years among patients without OSA [adjusted hazard ratio (HR), 1.12; 95% confidence interval (CI), 1.03-1.22; p=.0078]
• No higher risk of:
  o Death (HR, 0.94; 95% CI, 0.77-1.15; p=.54);
  o Composite of CV death, stroke/non–central nervous system embolism, TIA, or MI (HR, 1.07; 95% CI, 0.85-1.34; p=.57);
  o First major bleeding (HR, 1.18; 95% CI, 0.96-1.46; p=.11)

OSA associations w/ AF progression
• Not associated w/ higher risk of AF progression (HR, 1.06; 95% CI, 0.89-1.28; p=.51).

CPAP treatment association w/ outcomes in patients w/ AF & OSA
Less likely to progress to more permanent forms of AF versus patients w/out CPAP (HR, 0.66; 95% CI, 0.46-0.94; p=.021).

| | | | • HF-specific QoL (MLWHF)
| | | | • Daytime sleepiness

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
| 1,325 | **Exclusion criteria:**  
- Significant COPD with a forced expiratory volume in 1 s in 4 wk before randomization  
- $O_2$ saturation ≤90% at rest during d  
- Currently receiving PAP therapy  
- Cardiac surgery, PCI, MI or UA within the previous 6 mo  
- Cardiac resynchronization therapy implantation scheduled or performed within 6 mo prior to randomization  
- TIA or stroke within the previous 3 mo  
- $1^o$ hemodynamically-significant uncorrected VHD (obstructive or regurgitant) or any valvular disease expected to require surgery during the trial;  
- Acute myocarditis/pericarditis within the previous 6 mo  
- Untreated or therapy-refractory restless legs syndrome  
- Contraindication to the use of AutoSet CS2 because of symptomatic hypotension or significant intravascular volume depletion or pneumothorax or pneumomediastinum  
- Pregnancy | **Non-Significant Results**  
- Unplanned hospitalization for HF was not significantly higher with the intervention (43.1%) than control (41.3%; HR: 1.13; 95% CI: 0.95–1.33; p=0.16)  
- Of the lifesaving CV interventions, none were significantly higher with the intervention than control (p=0.08–0.61)  
- Unplanned hospitalization for any cause was not significantly lower with the intervention (67.9%) than control (68.0%; HR: 1.05; 95% CI: 0.92–1.20; p=0.47)  
- The NYHA class change was not significantly different with the intervention than with the control (p=0.46)  
- General QoL trends were not significantly higher with the intervention than with the control (p=0.09).  
- HF-specific QoL trends were not significantly higher with the  
- CV mortality was higher with the intervention (29.9%) than control (24.0%; HR: 1.34; 95% CI: 1.09–1.65; p=0.006).  
- 6MWT decreased over time and were significantly lower with the intervention than with the control (p=0.02).  
- Daytime sleepiness decreased over time and was significantly lower with the intervention than with the control (p<0.001).  

| 1,325 | **Optimized GDMT**  
- No new class of disease-modifying drug for prior ≥4 wk  
- AHI >15/h with ≥50% central events and a central AHI ≥10/h |  

Limitations:  
- Unblinded study - more likely to favor treatment group, particularly for QOL, but no QOL improvement seen  
- HF pts with reduced EF only  
- HF pts with predominantly CSA not obstructive sleep apnea.  
- Sample had very limited # of women but reflects epidemiology of CSA with HF/EF |

**Exclusion criteria:**

- Pregnancy
- MI
- UA
- Cardiac surgery within prior 3 mon, OSA

**Limitations:**

- Underpowered because trial stopped early for low enrollment

- LVEF significantly increased over time in CPAP-suppressed group (p<0.001)
- LVEF significantly increased in CPAP-suppressed vs. CPAP-unsuppressed (p=0.006) and vs. control (p<0.001) groups.
- No significant difference between CPAP-unsuppressed and control group (p=0.984)

- No significant difference in transplant free survival between CPAP and control groups (p=0.54)
- EF: Significant increase in EF between CPAP vs. control groups (p=0.02)
- Frequency of apnea and hypopnea episodes
- Significant reduction between CPAP vs. control groups (p<0.001)
- Mean Nocturnal SaO2
- Significant increase between CPAP vs. control groups (p≤0.001)
- 6MWCT: Significant increase in 6MWCT between CPAP vs. control groups (p=0.016)
- QoL: No significant difference between CPAP and control groups
### Neurohormones: Norepinephrine
- Significant reduction in CPAP vs. control groups (p=0.009)
- Atrial NP: No significant difference between CPAP and control groups

#### Kaneko et al. 2003 (103) 12660387

**Aim:**
To determine the effect of CPAP on LVEF when awake and daytime BP in pts with HF and OSA

**Study type:**
RCT

**Inclusion criteria:**
- HF due to ischemic or nonischemic dilated CM for >6 mo;
- LVEF <45% by radionuclide angiography
- NYHA class II–IV;
- Absence, in last 3 mo, of HF exacerbations while receiving optimal pharmacologic therapy at highest tolerated doses;

**Intervention:**
- CPAP n=12
- Control n=12

**1ᵉ endpoint:**
- LVEF when awake
- LVEDD
- LVESD
- Heart rate
- Daytime BP

**Significant Results**
- No significant improvement in arousals from sleep or sleep structure within or between groups (p=0.14–0.99)

**2ᵉ endpoint:**
- BMI
- Episodes of apnea and hypopnea
- Total
- Obstructive
- Central
- Desaturation index (# hr of sleep)
- Lowest oxyhemoglobin saturation (%)

---

### Limitations:
- 2ᵉ analysis of CANPAP data
- Did not classify arousals as being respiratory or non-respiratory related, and did not examine their timing.
<table>
<thead>
<tr>
<th><strong>Size:</strong> 24</th>
</tr>
</thead>
<tbody>
<tr>
<td>- OSA defined as ≥20 episodes of apnea and hypopnea/h of sleep of which &gt;50% were obstructive</td>
</tr>

**LVEDD**
- No significant difference for either group or between groups

**LVESD**
- Significant reduction in CPAP (p=0.009) but not control group and difference between groups was significant (p=0.02)

**Heart Rate**
- Significant decrease in CPAP (p=0.007) but not control group and difference between groups was significant (p=0.02)

**Daytime BP**
- Significant decrease in systolic BP in CPAP (p=0.02) but not control group and difference between groups was significant (p=0.008)
- No significant difference in diastolic BP for either group or between groups

**2° endpoint:**
- BMI

- No significant difference for either group or between groups

**Episodes of apnea and hypopnea**
- Total sleep time
- Stage I and II sleep (% of total sleep time)
- Stage III and IV sleep (% of total sleep time)
- REM sleep (% of total sleep time)
- Arousals/hr of sleep

**Limitations:**
- No placebo
- Small sample size
- Pts unblinded to group
was significant \( p=0.002 \)

**Obstructive**
- Significant reduction in CPAP \( p<0.001 \) but not control group and difference between groups was significant \( p<0.001 \)
- Central
- No significant difference for CPAP group or between groups

**Desaturation index (\# hr of sleep)**
- Significant reduction in CPAP \( p<0.001 \) but not control group and difference between groups was significant \( p=0.008 \)

**Lowest oxyhemoglobin saturation (%)**
- Significant increase in CPAP \( p=0.004 \) but not control group and difference between groups was significant \( p=0.01 \)

**Total sleep time**
- No significant difference for CPAP group or between groups

**Stage I and II sleep (% of total sleep time)**
- No significant difference for CPAP group or between groups

**Stage III and IV sleep sleep (% of total sleep time)**
- No significant difference for CPAP group or between groups

**REM sleep (% of total sleep time)**
| Mansfield et al. 2004 (104) 14597482 | **Aim:** To assess long-term effect of OSA treatment with nocturnal CPAP on systolic heart function, sympathetic activity, BP, and QoL in pts with HF | **Inclusion criteria:**  
- HF due to ischemic or nonischemic dilated CM for >6 mo;  
- LVEF <45% by radionuclide angiography  
- NYHA class II–IV;  
- Absence, in last 3 mo, of HF exacerbations while receiving optimal pharmacologic therapy at highest tolerated doses;  
- OSA defined as ≥20 episodes of apnea and hypopnea/h of sleep of which >50% were obstructive | **Intervention:** CPAP X 3 mo n=19  
**Comparator:** Control n=21 | **1° endpoint:**  
- LVEF  
- Overnight urinary norepinephrine excretion  
- BP  
- QoL  
**Significant Results 1° endpoint:**  
- Significant improvement in CPAP group (p<0.001) and vs. control group (p=0.04)  
- Overnight urinary norepinephrine excretion  
- Significant reduction in CPAP group (p<0.05) and vs. control group (p=0.036)  
**BP**  
- No significant difference in CPAP group or between groups  
**QoL**  
- Significant improvements in most domains within CPAP group  
**SF-36**  
- Significant improvements between groups in 4/8 domains  
  - Physical (p=0.03)  
  - Vitality (p=0.02)  
  - Social (p=0.03)  
  - Mental health (p=0.01) | **2° endpoint:**  
- Peak VO₂  
- NYHA class  
- Epworth sleepiness scale  
- BMI  
- AH events per h  
- Minimum SpO₂ saturation  
**Limitations:**  
- No placebo  
- Significant difference between groups in peak VO₂ and mean BP at BL  
- Dropout rate = 27%  
- Higher than expected death rate  
- Higher than expected rate of interventions initiated that may have effected end points  
- Small sample size with only 3 females |
<table>

**Post-MI ACEI Use**

2017 Heart Failure Focused Update Data Supplement

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
### SAVE, 1992  
**RCT**  
| 386652 (111) | To test the hypothesis that the long-term administration of captopril to survivors of acute MI who had baseline LV dysfunction but did not have overt HF requiring vasodilator therapy would reduce mortality, lessen deterioration in cardiac performance, and improve clinical outcome.  
| RCT | Beta-blockers 36%; Digitals 26%; Nitrates 51%  
| 2231; 1115; 1116 | Ischemic 100%  
| Alive 3 d after MI; LVEF <40%; >21 y of age, but <80; Killip class I — 60% (60% of the pts did not have even transient pulmonary congestion at baseline/the time of their acute MI; EF 31%; BP 113/70; HR 78;  
| Failure to undergo randomization within 16 d after the MI; Relative contraindication to the use of an ACEIs or the need for such an agent; SCI > 2.5 mg/dl  
| Mortality from all causes  
| Mortality from CV causes; Mortality combined with a decrease in the EF of at least 9 units in surviving pts; CV morbidity (development of severe CHF or the recurrence of MI); Combination of CV mortality and morbidity; 2 endpoints of severe HF (treatment failure): 1st, development of overt HF necessitating treatment with ACEI and 2nd, hospitalization to treat CHD.  
| 3.5 y |  
| Mortality from all causes was significantly reduced in the captopril group (228 deaths, or 20%) as c/w the placebo group (275 deaths, or 25%); the RR: 19% (95% CI, 3-32%; p=0.019).  RR:21% (95% CI, 5 -35%; p=0.014) for death from CV causes, 37% (95% CI, 20-50%; p<0.001) for the development of severe HF, 22% (95% CI, 4-37%; p=0.019) for CHF requiring hospitalization, and 25% (95% CI, 5-40%; p=0.015) for recurrent MI.  

### AIRE 1993  
**RCT**  
| 8104270 (112) | Investigated the effect of therapy with ACEI ramipril, on survival in pts who had shown clinical evidence of HF at any time after an acute MI. Also, to compare the incidences of progression to severe or resistant HF, nonfatal reinfarction and stroke between the 2 groups.  
| RCT | 2006; 1014; 992  
| Aged ≥ 18 y, with a definite acute MI 3-10 d before randomization; Clinical evidence of HF at any time since acute MI  
| Use of an ACEI considered to be mandatory  
| Mortality from all causes  
| 1.3 y |  
| Mortality from all causes was significantly lower for pts on ramipril compared to pts on placebo. RR: 27%; 95% CI: 11-40%; p<0.002. Prespecified secondary outcomes: risk reduction of 19% for the 1st validated outcome—namely, death, severe/resistant HF, MI, or stroke (95% CI: 5% - 31%; p=0.008).  

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
To determine whether pts who LV dysfunction soon after MI benefit from long-term oral ACE inhibition.

RCT

Beta blocker 16%; Calcium antagonist 28%; Diuretic 66%; Nitrates 33%; Digoxin 28%.

Consecutive pts >18 y hospitalized with MI; Criteria for MI: chest pain or electrocardiographic changes, accompanied by >2X increase in 1 cardiac enzymes; LV dysfunction (EF <35%); NYHA class 1 - 41%; BP 121/76; HR 81

Contraindication to ACEI or a definite need for them; Severe, uncontrolled DM; Hyponatremia (<125 mmol/L); Elevated SCR level (2.3 mg/dL);

Death from any cause

Death from a CV cause, sudden death, Progression to severe HF (hospital admission for HF, death due to progressive HF, or HF necessitating open-label ACEI); Recurrent infarction (fatal or nonfatal); Change in the wall-motion index (EF)

The mortality from all causes at 1 y was 24%.

24 lives were saved after 1 mo of treating 1,000 pts

During the study period, 304 pts in the trandolapril group died (34.7%), as did 369 in the placebo group (42.3%). RR: 0.78 (95% CI, 0.67 - 0.91; p=0.001).

In every subgroup, treatment with trandolapril was associated with a reduction in risk.

ACEI indicates angiotensin-converting-enzyme inhibitor; AF, atrial fibrillation; AIRE, Acute Infarction Ramipril Efficacy; APE, acute pulmonary embolism; ATLAS, Assessment of Treatment with Lisinopril and Survival; BP, blood pressure; CAD, coronary artery disease; CHD, chronic heart disease; CHF, congestive heart failure; CONSENSUS Cooperative North Scandinavian Enalapril Survival Study; Ct, creatinine; CV, cardiovascular; CW, compared with; DM, diabetes mellitus; ED, emergency department; FU, follow-up; HF, heart failure.

CIBIS II Investigators and Committee Members (1999) 1023843 (119) Investigate the efficacy of bisoprolol in decreasing all-cause mortality in chronic HF. RCT - multicenter double-blind randomised placebo controlled trial (Europe) Diuretics + ACEI; [amiodarone allowed–14-16%] Documented ischemic 50% NYHA class II or IV EF: <35% 18-50 y old Uncontrolled HTN; MI/UA within previous 3 mo; PTCA/CABG within previous 6 mo; AV-block >1st degree w/o PPM; Heart rate < 60 bpm; resting SBP <100mmHg; renal failure; Reversible obstruct lung disease; Use of beta blocker Moderate to severe. Mean BP: 130/80; Mean HR: 80; Mean EF: 28%; Mean LVEDD: 6.7 cm; AF: 20% All-cause mortality All-cause hospital admissions All CV deaths Combined endpoints Permanent treatment withdrawal 13.2% Placebo group 8.8% Treamt1 group 11.4% 1.3 y HR: 0.66 (95% CI: 0.54-0.81); p=0.0011

MERIT-HF; MERIT study Group; (1999) 10376614 (120) Investigate whether Metoprolol CR/XL lowered mortality in pts with decreased EF and symptoms of HF. RCT – multicenter double-blind randomised placebo controlled trial (Europe + USA) Diuretics + ACEI [Amiodarone NOT allowed] 3991; 1991; 2001 Ischemic 65% NYHA IV; 40-85 y; LVEF: <40% (36-40 if 6 min walk <450m); heart rate >68 bpm MUGA within 28 d; Contraindication or current use of beta blocker; PTCA/CABG within 4 mo Planned transplantation or ICD; Heart block >1st degree w/o PPM; SBP <100mmHg Mild to severe. Mean BP: 130/78; Mean HR: 78; Mean EF 28%; AF 16-17% All-cause mortality All-cause mortality in combination with all-cause admission to hospital N/A 11.0% Placebo group 7.2% Treamt1 group 11.4% 1.0 y Treatment of 27 pt for 1 y can prevent 1 premature death. 0.68 (95% CI: 0.53-0.81); p=0.00009

COPERNICUS: Packer et al; (2002) 12390497 (121) Investigate whether Carvedilol is beneficial in severe HF. RCT–double blind Diuretics (PO or IV) + ACEI (or ARB); [Amiodarone allowed 17-18%] 2289; 1156; 1133 Ischemic 67% Evoefomic NYHA class IV, LVEF <25%; No positive inotropes or vasodilators within 4 d Pt required hospitalizing intensive care; Use of positive inotropes or IV; vasodilators within 4- d; Coronary revascularization/MICVA/ sign VT or VF w/in 2 mo; SBP < 85 mmHg, Heart rate <82; O2 >2.8 mg/dL Severe Mean BP: 1237/69; Mean EF 20%; All-cause mortality Combined risk of death or hospitalization-any reason; Combined risk of death or hospitalization–CV reason; Combined risk of death or hospitalization–HF reason; Pt global assessment 19.7% placebo [24.0% in pts with recent or recurrent cardiac decompensations] 18.5% in placebo group 11.4% in Carvedilol group 10.4 mo Treating 1000 pt for 1 y led to savings of 70 premature deaths p=0.0014

SENIORS: Flather et al; (2005) 16642700 (122) Assess effects of the beta blocker Nebivolol in pts >70 y regardless of EF. RCT Diuretics + ACEI (+aldosterone antagonist in 29%) 2128; 1067; 1061 Prior to CAD in 69% Age >70 CHF with 1 of the following: hospitalization with CHF w/in a year or EF <35% w/in the past 6 mo New HF Therapy w/in 6 wk or change in drug therapy within 2 wk Contradication to beta blockers, current use of beta blockers Significant renal dysfunction CVA w/in 3 mo. Mild to severe Mean BP: 139/81; Mean HR: 78; Mean EF 36% (13 with EF >35%) Composite of all-cause or CV hospital admission N/A All-cause mortality Composite of all-cause or CV hospital admissions All cause hospital admissions CV hospital admissions CV mortality Composite of CV mortality or CV hospital admissions NYHA class assessment; 6 MWT N/A 1.75 y Absolute risk reduction 4.2%; 24 pts would need to be treated for 21 mo to avoid one event RR: 0.96; 95% CI: 0.74-0.99; p=0.038

A Trial of the Beta-Blocker Bucindolol in Pt with Advanced Chronic HF The Beta-Blocker Evaluation of Survival Trial Investigators 11386264 (123) Designed to determine whether bucindolol hydrochloride, a nonselective beta-adrenergic blocker and mild vasodilator, would reduce the rate of death from any cause among pts with advanced HF. RCT ACEIs (if tolerated) [91% ACE; 7% ARB]; for at least 1 mo. Before the publication of the results of the DIG trial, 12 digoxin therapies were 2708; 1354; 1384 Ischemic 59% NYHA class III or IV EF: <35% >15 y Reversible cause of HF present Candidates for heart transplantation Cardiac revascularization procedure within the previous 60 d UA Heart rate <50 bpm, SBP <80 mmHg Decompensated HF. NYHA III or IV (62% class III) EF 23%; HR 82; BP 117/71; AF 12% Death from any cause Death from CV causes (death due to pump failure or an ischemic event or sudden death) Hospitalization for any reason Hospitalization because of HF Composite of death or heart transplantation LVEF at 5 and 12 mo MI, QD, and any change in For pt in NYHA functional class III, the annual mortality rate was 16% in the placebo group; For pt with NYHA class IV, the annual mortality rate in the placebo group was 28% Overall: annual mortality of 17% in placebo group cvw N/A ~<2 y 449 pt in placebo group (33%) died, 411 pt in the bucindolol group (30%); HR: 0.90; 95% CI: 0.78-1.02; unadjusted p=0.10; adjusted p=0.13
and to assess its effect in various subgroups defined by ethnic background and demographic criteria—specifically women and members of minority groups.

**COMET: Poole-Wilson et al; (2003) 12853193 (124)**

To compare the effects of carvedilol and metoprolol on clinical outcome in pts with HF

| RCT | Diuretics, ACEIs | NYHA class II/IV EF <35% Previous CV admission | N/A | Mild to severe | All-cause mortality Composite endpoint of all-cause mortality, or all-cause admission | N/A | N/A | N/A | 4.8 y | All-cause mortality 34%

**CIBIS III: 2005; 16143696 (125)**

Sufficient data do not currently exist to establish the optimal order of initiating chronic HF therapy (ACEI vs. beta blocker). This was the objective of the CIBIS III trial—compared the effect on mortality and hospitalization of initial monotherapy with either bisoprolol or enalapril for 6 mo, followed by their combination for 6 to 24 mo.

| Diuretics 84%; Digoxin 32% | CAD 62% >65 y, NYHA class II or III, and LVEF <35% (By echo within the 3 mo) Clinically stable HF (without clinically relevant fluid retention or diuretic adjustment within 7 d) Treatment with an ACEI, an ARB, or a beta blocker for >7 d before randomization Heart rate at rest <60 bpm without a functioning pacemaker Supine SBP <100 mm Hg at rest SCr <220 mmol/L AV block >1° without a functioning pacemaker Obstructive lung disease contraindicating bisoprolol treatment | N/A | NYHA II or III; mild to moderate CHF LVEF 29%; Heart rate 79%; SBP 134 The primary endpoint was time-to-the-first event of combined all-cause mortality or all-cause hospitalization Combined endpoint at the end of the monotherapy phase and the individual components of the primary endpoint, at study end and at the end of the monotherapy phase. CV death CV hospitalization | N/A | N/A | Mean of 1.22±0.42 y (maximum of 2.10 y). In the ITT sample, 178 pt (35.2%) with a primary endpoint in the bisoprolol-1st group, and 186 (36.8%) in the enalapril-1st group (absolute difference -1.6%; 95% CI: -7.6 to 4.4%; HR: 0.94; 95% CI: 0.77–1.16; noninferiority for bisoprolol-first versus enalapril-1st treatment p=0.019) |

ACEI indicates angiotensin-converting-enzyme inhibitor; AF, atrial fibrillation; ARB, angiotensin receptor blocker; AV, atioventricular; BP, blood pressure; CABG, coronary artery bypass graft; CHF, congestive heart failure; CIBIS II, Cardiac Insufficiency Bisoprolol Study II; COMET, Carvedilol Or Metoprolol European Trial; COPERNICUS, carvedilol prospective randomized cumulative survival; CR, creatinine; CR/XL, controlled release/extended release; CV, cardiovascular; CVA, cerebrovascular accident; c/w, compared with; DIG, Digitalis Investigation Group; EF, ejection fraction; HF, heart failure; h/o, history of; HR, hazard ratio; ICD, implantable cardioverter defibrillator; ITT, intent to treat; MERIT-HF, Metoprolol CR/XL Randomised Intervention Trial in Congestive Heart Failure; MI, myocardial infarction; MWT, minute walk test; NYHA, New York Heart Association; PPM, permanent pacemaker; PTCA, percutaneous transluminal coronary angioplasty; Pts, patients; QoL, quality of life; RCT, randomized control trial; RR, relative risk; SBP, systolic blood pressure; SCr, serum creatinine; UA, unstable angina; USA, United States of America; VF, ventricular fibrillation; VT, ventricular tachycardia; and w/o, without.
